

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

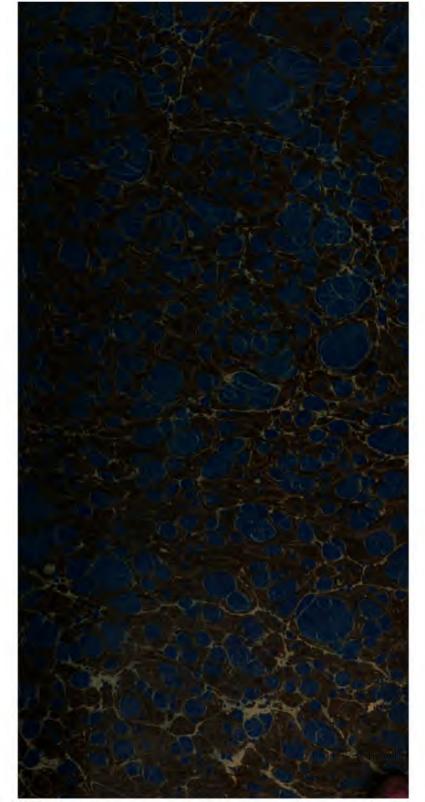

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

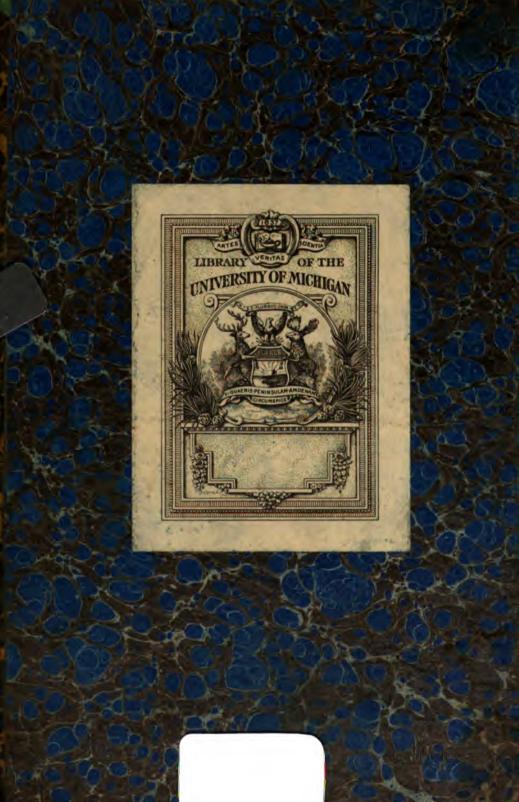

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

CONNAISSANCE DES TEMS

DES MOUVEMENS CÉLESTES,

A L'USAGE

DES ASTRONOMES

ET ·

DES NAVIGATEURS, POUR L'AN 1837;

PUBLIÉE PAR LE BUREAU DES LONGITUDES.

PARIS, BACHELIER, IMPRIMEUR-LIBRAIRE

DU BUREAU DES LORGITUDES, DE L'ÉCOLE POLITECHNIQUE, etc., QUAI DES AUGUSTINS, N° 55.

1834.

5 1 2 2 1 A

La Connaissance des Tems, sans les Additions, ayant été portée depuis deux ans de 216 à 366 pages, pour l'utilité des marins, le Bureau des Longitudes a arrêté que le prix en serait de CINQ fr. au lieu de 4 fr., et que le prix de la Connaissance des Tems, avec les Additions, serait fixé à SEPT fr. au lieu de 6 fr.

ORDONNANGE DU ROI sur le service des Officiers, des Élères et des Mattres L bord des bâtimens de la Marine Royale. Paris, Imprimerie royale, 1827, in-80, 6 fr.

BEZOUT. TRAITE DE NAVIGATION, nouvelle édition, revue et augmentée de Notes et d'une Section supplémentaire, ou l'on donne la manière de faire les calculs des Observations, avec de nouvelles Tables qui les facilitent; par M. ne Rosser, ancien Capitaine de Vaisseau; Directeur-Adjoint du Depôt général des Cartes, Plans et Archives de la Marine; Membre de l'Institut et du Burest des Longitudes, etc., novembre 1814, 1 vol. 11-8° avec 10 planches. Prix, 6 fr. pour Paris, et 7 fr. 50 c.

franc de port.

RECUEIL DE TABLES UTILES A LA NAVIGATION, ouvrage traduit de l'anglais de John Villiam Norre, précédé d'un Trafté de Navigation practique, consessant set qui est nécessaire et indispensable à toutes les classes de Marins; enrichi d'un Vocabulaire des termes les plus usités dans la Marine : le tout extrate des meilleurs Auteurs français, espagnols, anglais, recueilli et mis en ordre par M. Violeire; un fort vol. in-80, 1815. Prix, 9 fr. pour Peris, et 11 fr. franc da port.

TABLEAUX DES VENTS, DES MAREES ET DES COURANS qui out été observés sur toutes les mers du globe; avec des Reflexions sur ces phononiences per Сн. Ronne, etc.; enrichis d'une carte, 2 vol. in-c., 1817, Prix 12 fr. pour Paris, et 16 fr. franc de part par la poste. et 16 fr. franc de port par in poste.

TRAITÉ ÉLÉMENTAIRE D'HYDROGRAPHIE appliquée à toutes les parties du pilotage, à l'usage des Elèves ou Aspirans de la Marine militaire et marchande; par L. D. LASSALE, 1 vol. in-8., 1817. Prix 6 fr. pour Paris, et 7 fr. 50 c. franc de port

par la poste.

TRAITE DE NAVIGATION, ouvrage appronvé par l'Institut de France, et mis à la portée de tous les Navigateurs, par M. D'uneureur, aucien Officie de Matine, et mis à la Professeur de Mathematiques au Collége Louis-le-Grand, etc., I vol. in-4° avec figures.

Prix, 20 fr. pour Paris, et 26 fr. frenc de port.

DICTIONNAIRE DE LA MARINE FRANÇAISE par Romaz, in-8° avec pl. et 157 pavillons, flammes et guidons coloriés avec soin. Pdx,

TABLES DES PRINCIPALES POSITIONS DU GLOBE, recueillies et mises en ordre d'après les autorités les plus modernes, renfermant les expressions de portient de tous les points maritimes connus, classés par ordre alphabétique, avec les nomb des abservateurs on des autours autopuds les chiffres sont dub, sus ; par Connun.

In-8, 1838.

12 fr.

DICTIONNAIRE DES TERMES DE MARINE français-espagnols at respandols français, auquel on a joint un Traité de prononciation pour chaque Langue; par C. Laguater et C. J. Perre. In-8., 1840.

TRAITE PRATIQUE DU GREMENT des vaisseaux et autres bâtimens de mer, 2 froit in-48.

RAITE PRATIQUE DU GRESTELLE des de la Marine, per Lesceller, 2 voli in-19, ouvrage public pour l'instruction des dities de la Marine, per Lesceller, 2 voli in-19, 27 fri dont un de planches

DESCRIPTION et Usages de l'Uragographie, deserés sons l'imprecion de M. Bou-vand, astronome, membre de l'Académie et du Bureau des Longitudes; par Dign. Une foutile grand-night Nota. La position des étoiles est déterminée d'après le nouveau catalogue qui s'été

reduit à cet effet par M. Marion, calculateur du Bureau des Longitudes, otc.

IMPRIMERIE DE BACHELIER, RUE DU JARDINET, Nº 12.

AVERTISSEMENT.

gingshissing in the

Ce volume est le 159° d'une Éphéméride qui n'a jamais souffert d'interruption, depuis la publication du 1er volume, en 1679, par Picard, mais qui, en différent tems, a reçu dans sa composition des modifications qui sont indiquées dans les volumes de 1808, 1817 et 1820.

Les nouveaux changemens adoptés par le Bureau des Longitudes et annoncés dans le volume de 1832, n'ont puêtre introduits qu'en partie dans les volumes de 1833, 1834 et 1835, mais cette année de même que pour le volume de 1836 ils ontété opérés entièrement.

Astuellement on n'emploie plus qu'une seule espèce de tems : tout est rapporté au tems moyen : les positions du Soleil, de la Luna et des planètes, sont données pour midi et minuit moyen; les levers et couchers, les passages au méridien de ces astres, sont exprimés en tems moyen. On trouve en regard des élémens les plus importans, les plus usuels de l'Annuaire, les différences qui an rendeut l'amploi plus commode et plus sûr pour les marins et les astronomes. Au reste, on peut consulter pour plus de métails, l'explication et l'usage des divers articles de l'Annuaire, page 368.

Les calquis ont été faits, sous l'inspection du Bureau des Longiteades, par MM. Marion et Lebaillif-Mesnager, sur les Tables corrigées de Delambre, pour le Soleil; sur celles de Burckhardt, paur la lune; sur celles de Delambre, pour les satellites de Jupiter; sind celles de M. Bouvard, pour Jupiter, Saturne et Uranus; sur celles de M. Lindenau, pour Mercure, Vénus et Mars.

A la suite du calendrier on trouve les positions apparentes de

67 étoiles principales, et pour le tems moyen les distances de la Lune aux quatre planètes Vénus, Mars, Jupiter et Saturne. Ces distances ont été déduites des longitudes et latitudes calculées directement par les tables de M. Bouvard, pour Jupiter et Saturne, et par les tables de M. Lindenau, pour Vénus et Mars.

La seconde partie renferme, sous le titre d'Additions, des Mémoires lus dans les séances du Bureau des Longitudes.

Errata de la Connaissance des Tems de 1857.

Additions.

Page 30, ligne 1, au lieu de longitude, Mes longueux.

POUR L'AN 1837.

Année 6550 de la période Julienne.

2500 de la fondation de Rome, selon Varron.

2524 depuis l'ère de Nalonassar, fixée au mercredi 26 février de l'an 3067 de la période julienne, ou 747 ans avant J.-C. selon les chronologistes, et 746 suivant les astronomes.

2613 des Olympiades, ou la 1¹⁰ année de la 654° Olympiade, commence en juillet 1837, en fixant l'ère des Olympiades 775 \frac{1}{2} ans avant J.-C. ou vers le 1¹⁰ juillet de l'an 3038 de la période Julienne.

1252 des Turcs commence le 18 avril 1836 et finit le 6 avril

1252 des Turcs commence le 18avril 1836 et finit le 6 avril 1837, selon l'usage de Constantinople, d'après l'Art de

#### TABLEAU des plus grandes Marées de l'année 1837.

Le Soleil et la Lune, par leur attraction sur la mer, octasionent des marées qui secombinent ensemble et qui produisent les marées que nons observous. La marée composée
est très grande vers les syzygies, ou les nouvelles et pleines Lipnes. Alors elle est la somme
des marées partielles qui conicident. Les marées des syzygies ne sont pas toutes également
fortes, parce que les marées partielles qui concourent à leur production, varient avec les
déclinaisons du Soleil et de la Lune, et les distances de ces astres à la Terre: elles
sont d'autant plus considérables, que la Lune et le Sòleil sont plus rapprochés de la
Terre et du plan de l'équateur. Le Tablegu ci-dessous renferme les hauteurs de toutes
ces grandes marées pour l'année 1837. M. Largeteau les a calculées par la formule que
le marquis de Laplace a donnée dans la Mécanique célèste, tome II, p. 289; on a
pris pour l'unité de hauteur la moitié de la bauteur moyenne de la marée totale, qui
arrive un jour ou deux après la syzygie, quand le Soleil et la Lune, au moment de
la syzygie, sont dans l'équateur et dans leurs moyennes distances à la Terre.

	•	, ,	
Jours et heures de la syzygie.	de la murée.	Jours et heures de la syzygie.	Hauteur de la marce.
Janvier (N. L. le 6 hith. P. L. le 21 à 7.	56' soir 0,95	Juillet {N. la. le 2	h gh3g' soir 0,70° h 11. 0. soir 0,94
Février. [N. L. le 5 à 10. P. L. le 20 à 2.	17. matin. 1,63 33. soir 0,85	Août P. L. le 16	k o. 29. soir 0,74 h 5, 48. matin. 1,05

•		[N. L, le 27	1 2.45. soir. 0,87

On a remarqué que, dans nos ports, les plus grandes marées suivent d'un jour et demi la nouvelle et la pleine Lune. Ainsi, on aura l'époque où elles arrivent, en ajoutant un jour et demi à la date des syzygies. On voit par ce Tableau que les plus fortes marces de l'année 1837 sont peu considérables : les plus grandes sont celles du 6 février, du 8 mars, du 6 avril, du 17 soût, du 16 septembre et du 15 octobre; quoiqu'elles soient heaucoup moindres que celles qui arrivent dans le voisinage du maximum, elles pourraient occasioner des inondations, si elles étaient favorisées par les vents.

Voici l'unité de hauteur pour quelques ports :

Unité de hau	teur.	Unité de	e hanter
Port de Brest 3mg Lorient 2, 2 Cherbourg. 2, 7 Granville 6, 3	4	Port de Saint-Mâlo Audierne Croisic Disppe	2, 00 2, 68

L'unité de hauteur à Brest est connue avec une grande exactitude. Dans une suite d'observations faites pendant 16 ans, depuis 1806 jusqu'en 1823, on a choisi les hautes

et basses mers équinoxiales, comme étant à peu près indépendantes des déglinaisons du Soleil et de la Luns. La moyenne de 384 de ces observations a donné 6m,415 pour la différence entre les hautes et basses marées; la moitié de ce nombre ou 3m,21 est ce qu'on appelle l'unité de hauteur

Si l'on veut connaître la hauteur d'une grande marée dans un port, il faudra multiplier la hauteur de la marée prise dans le Tableau précédent par l'unité de hauteur qui

Exemple. Quelle sera à Brest la hauteur de la marée qui arrivera le 16 septembre 1837, un jour et demi sprès le syzygie du 14? Multipliez 3m,21, unité de hauteur à Breat, par la hauteur 1,12 de la l'Isble, vous aurez 3m,60 pour la hauteur de la mer au-dessus du niveau moyen qui aurait lieu si l'action du Soleil et de la Lune venait à cesser.

#### TABLES DE RÉFRACTIONS.

Ces Tables sont extraites de celles qui ont été publiées par le Bureau des Longitudes. Elles ont été calculées d'après la formule de Laplace (Mécanique oéleste, tome IV, page 271), par MM. Bouvard et Arago. Delandre a déduit la sonstante d'un grand nombre d'observations de Piazzi et de plusieurs centaines de hauteurs du Soleil, qu'il avait observées à Bourges depuis 70° jusqu'à 90° 20′ de distance au zénith; la valeur de cette constante s'accorde avec le résultat des expériences de MM. Biot

et Arago, sur le pouvoir réfringent de l'air. La première Table donne les réfractions moyennes, dont les navigateurs peuvent souvent se contenter; mais pour les cas qui demanderaient une plus grande précision, on a donné dans la séconde table les facteurs par lesquels on doit multiplier la réfraction moyenne, pour la réduire à celle qui répond à la pression barométrique et à la tem-pérature de l'air au moment de l'observation.

Pour abreger l'opération, on multipliera, l'un par l'autre, les deux facteurs, et le produit servira ensuite de multiplicateur pour la réfraction moyenne.

Exemple. Hauteur observée 3° 45′ 18″ = 3° 45′ 3′ Pour 3° 40′ Table I	mètre 029741 Facteur 0.975
o, <b>3</b> — 0,73	0.975
Réfraction moyenne 12' 22,72 = 742"72	3
Pour - 0.02 14,85 - 0.002 1,48	Produit + 0.978 ou 1 - 0.022
Réfraction corrigée 12. 6,39	· -
Exemple. Méchain observa la spême étoile à	Table II.  Baromètre 0.766 1.008 Therm + 8.125 1.007 8
Réfraction moyenne 12. 24, 26 = 744"26 Pour + 0.01 + 7.44 + 0.005 + 3.72 Réfraction corrigée 12' 35"4 755.42	Produit des facteurs. 7.015

Ces Tables supposent le baromètre à 76 centimètres, et le thermomètre à 10° centigrades,

Pour 10 d'augmentation, diminues de 5 unités les nombres des deux Tables.

Pour un de plus, augmentez de 16 unités les nambres centimètre de moins, diminuez des deux Tubles.

Pour interpoler entre des nombres calculés de 12 heures en 12 heures, prenez-en quatre; donnez le signe + aux trois différences premières si les nombres croissent, et le signe - s'ils décroissent; les différences secondes seront de même signe que les premières, si celles-ci croissent, et de signe contraire si elles décroissent. Entrez dans la Table avec l'heure et la demi-somme des deux différences secondes, et donnez à la correction un signe contraire à celui des différences secondes.

Différences secondes { positives.... ajoutez { la correction de la Table.

On réduira les minutes en regardant les nembres de la Table comme des minutes et des secondes.

On réduira les secondes en prenant les nombres de la Table pour des secondes et des tierces; mais on donvertira les tierces en fraction de seconde, en mettant 1 dixième pour 6°; 2 dixièmes pour 12°, et ainsi de suite.

## TABLE DES POSITIONS GÉOGRAPHIQUES.

Deputs pingieurs anaées cette Tablé avais cests de racevoir les perfectionnement dont elle a perfection pour sur terme au niveau de la science, sa resonte entière était devenue néseaulres est la Grographie sait journellement des progrès. Pour parvenir à ce but on a du technicher d'abord l'arigine de toutes les positions qui étaient contenues dans la Table précédente; estin de conserver coutes celles qui étaient sondées sur des autorisés que l'on pour les principal que l'on s'est d'abord proposé. Une grande partie des positions a été ainsi renouvelée; mais comme la recherche des autorisés sur lesquelles étaient fondées les aucieones déterminations a exigé un travail très long, pour éviter qu'il l'avenir un pareil inconvénient se renouvelle, on a pensé qu'il était nécessaire d'indiquer dans la Table même l'origine de ces déterminations.

Le Baresu des Congitudes a arrêté aussi que cetta Table sersit divisée, par pays, en un certain nombre de parties, ainsi qu'elle l'avait été jusqu'en 1809. Cette division a principalement pour but de rapprocher les points qui peuvent se trouver liés les uns aux autres, soit par des opérations géodésiques, soit par des différences de longitude obtantes par le moyen de montres marines. Le seul cas où cette division peut présenter quelque désavantage est celui dans lequel on voudrait chercher la position d'un point dont où que chouafirait que le nom; ou serait obligé alors de chercher successivement dans plugiones divisions, jusqu'à ce qu'on arrivat sur le point; mais chacune d'elle étant disposés/par ordre alphabétique, les recherches ne sauraient être léngues. Ce cas, au reste, doit stravels si rarement, qu'on n'a pas ure devoir a'y arrêter. La Table a donc été divisée en seize parties ou sections, savoir :

. Prauce.

II. Iles Britanniques.

III. Hollande et Belgique.

D M. S

IV. Danemark , Suède et Norvége.

V.+Russie.

VII Allemagne on Confederation germa-

VII. Hongrie, Delmatio, Iles Ionicanes,

8 Giffre et Purquie d'Europe

VIII. Indie et Suisse.

IX. Espagne et Portugalist

X. Asie.

XI. Grand Archipel d'Asib et Nouvelle-Hollande.

XII. Iles de la Mer da Sud-

XIII. Afrique et lles éparses de la mer des Indes et de l'Océan atlantique,

XIV. Amérique septentrionale,

XV. Antilles.

XVI. Amerique méridionale.

Cette disposition ayant permis de supprimer la colonne destinée à contenir les noms fles contrées, cela a fourni le moyen de donner dans une dernière colonne les noms des superirs des éterminations adoptées et ceux des personnes qui les ont calculées ou disputées, ou l'indication des ouvrages dans lesquels on les trouve, on a autant que possible findique le volume en chiffres romains et la page en chiffres ordinaires, afin de faciliter les recherches. Pour renfermer tout cela dans l'espace donné, il a fallu nécessaigement adopter des abréviations dont nous allous donner iet l'explication.

1789....1837. Toutes les fois que la position se trouve rapportée ou discutée dans un des volumes de la Connaissance des l'ems, on a indiqué seulement l'année; ainsi 11789.328 indique que cette position a été donnée dans la Connaissance des Tems, pour 1789, page 328. Celles qui ont été discutées cette année sont indiquées 1837.

B. 1792. Les Éphéractides de Berlin publices par Bode out été désignées par B, 2702.
L'indication B. 177, 2me, 3me supplément signifie les supplément à ces Éphérac-

rides, publiés par Bode.

Z₁ et Z₂. La correspondance astronomique de M. de Zach, tant allemande que française, a fourni un grand nombre de déterminations. La correspondance allemande, ou Monalliche correspondenz, est indiquée par la lettre Z₂, et la correspondance française par Z₃.

S. Le Journal astronomique que M. Schumecher public à Altona sous le titre de Astronomische Nachrichten, est désigné per une S.

P. La plupart des positions de la France ent été tirées de la neavelle description récométrique de la France, ou Précis des apérations qui errent de fondemeus à la nouvelle carte du royaume, par M. Puissant. Cet ouvrage est désigné par en P. Quelques-unes de ces positions ayant été prises sur les tableaux qui récompagneut chacune des feuilles de la nouvelle carte, on a indiqué alors après l'abréviation F. l'et nom de la feuille à lequelle ce point apparatient. Les chiffres qui se écouvent à la suite du nom indiquent, en mêtres, l'elévation du point au-dessus du niveau de la mer; lorsque cette hauteur a rapport au sommet de l'édifice et non pas au sof, on les a renfermés entre deux parenthèses.

M. L'ouvrage intitulé, An account of the operations carried on for accomplishing a Trigonometrical Survey of England and Wales, by W. Mudge, and J. Daiby, qui a fourni une grande partie des positions d'Angleterre, a été désigné par M.

- Klint. Les positions données par Klint ont été tisées de l'ouvrage initiulé Description des côtes de la Mer Baltique et du golfe de Finlande, par Gustave Klint, Stockholm, 1815.
- Carte danoise. Les cartes danoises qui sont citées comme autorités sont des cartes du Cattegat, du Skagerack et des Belts, publiées en 1830, 31 et 32, par le Dépôt des cartes de Copenhague.

Fl. L'ouvrage de M. de Fleurieu intitulé Fondemens des cartes du Cattegat et de la Baltique, 1794, est indiqué par l'abreviation Fl.

Carta del mare Adriatico. Plusieurs points de l'Italie et de la Dalmatic sout tirés de la Table qui accompagne un atlas de la mer Adriatique, intitulé Carta de cabotaggio del mare Adriatico, publié par l'Institut géographique de Milan, en 1824.

K. Les mémoires hydrographiques pour servir d'analyse à l'atlas de l'Ocean l'acisique,

par Krusenstern, sont désignés per K.

- As. Res. Les Asiatic Researches ayant aussi fourni beaucoup de points dans l'Inde, sont désignées par l'abréviation As. Res. On observera toutefois que pour le tome X de ce recueil, auquel on a emprunté le plus grand nombre de positions, on n'a pu consulter que l'édition in-8° publiée à Londres en 1811; pour les autres, qui sont postérieures, c'est l'édition in-4°.
- O. L'ouvrage de M. Oltmanns, intitulé Untersuchungen uber die Geographie des Neuen-Continents, Paris, 1810, est désigné par O.

Les autres indications portant les noms des auteurs en toutes lettres n'exigent pas d'explication; ainsi les noms de D'Entrecasteaux, King, Flinders, etc., indiquent suf-fisamment l'origine de ces positions, et où l'on peut les vérifier.

Les Additions pour l'année 1836 contiennent une explication détaillée de cette Table, on trouvers dans les Additions de cette année 1837 les raisons des changemens qui y ont été faits.

POSITIONS géographiques; ou Table des latitudes des principaux lieux de la Terre, et de leurs longitudes ou différence de méridiens par rapport à l'Observatoire royal de Paris:

#### DE L'ANNUAIRE ET DES TABLES.

chacter year

Obliquité apparente de l'Écliptique, page 5.

Cette obliquité est calculée sur les Tables solaires de Delembres en supposant l'obliquité movenne de 23° 27' 57' en 1800, et la diminution séculaire de 48". Cette obliquité moyenne a été déterminée par douze solstices, tant d'hiver que d'été, observés par Delambre, avec le cercle répétiteur de liorda; il n'a guère trouvé que 4 le 5 de différence entre l'hiver et l'été, en se servant des réfractions de Bradley; et en prenant 48" 50' 14" pour la hauteur du pole à l'Observatoire de Paris. Pour faire évanouir cette légère différence, il lui a suffi d'augmenter un peu la réfraction de Bradley pour 65°. Cette augmentation le forçais de diminuer de 2° la bauteur du pôle, qu'il avait aussi déterminée puir 1800 observations faites avec le cercle de Burda; en se servant des réfractions de Bradley. On aurait à fort peu près les mêmes résultats avec la Table de réfractions de Laplace ; du moins la différença qui résterait entre les suistices d'hiver et d'été ne passeruit guère 1"s Cette Table réduit la latitude de Paris à 48° 50' 13', 6, d'après les cherreitions de Delambre: et à 48°50' 13' suivant les dernières observations de Méchain. ( Payes Base du système métrique, tome II , page 64s.) MAL Aragu et Mathieu, on faisant aussi usage des Tables de réfractions de Juphase, sut trouvé 48°50′ r3°, 2 pour la latitude de la face méridionale de l'Observatoire, par un grand nombre d'observations de la polaire, faites avac un cercle répétiteur d'un mêtre de diamètre, de Reichenbach. (Noy. Connaissance des Terns de 1816, page 355.) D'après ces déterminations, on neut adopter 48º 50' 13", a pour la latitude de la face méridiensie de l'Observatoire.

Les déclinaisons du Soleil calculées pour tous les jours du mais, annposent l'obliquité moyenne 23° 27′ 57° — o", 48¢, s étant le nombre d'années
écoulées depuis 1800. Pour une seconde de différence dans l'obliquité,
la déclinaison changerait de o", 97 sin  $\bigcirc$  — o", e17 sin  $\bigcirc$   $\bigcirc$  ou de " cot se
tang D = 2°, 315 tang D. Voici une petite table de correction extendée sur
cette dernière formule.

Avant de faire connaître en détail la composition de chaque page d'un même mois, il importe d'indiquer les dispositions générales : on trouve

en regard, dans les pages 1 et 2, les principaux élémens du Soleil, et ceux de la Lune dans les pages 3,14,5 at 6,1 TA, 11 TA

#### PREMIÈRE PAGE DE CHAQUE MOIS.

On a mis, dans la troisième colonne, la fraction de l'année pour chaque jour. Dans les quatrième et cînquième colonnes, on a marqué en tems moyen l'heure du lever et du coucher apparent du centre du Soleil à Paris, c'est-à-dire que l'on a tenu compte de l'effet de la réfraction, qui fait paraître à l'horizon les astres qui se trouvent 33 minutes au-dessous de consensated to the sound of a first of the same of the first of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of th Top some a to the some of the property of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the solution of the Compre d'augmentation d'ascension droite est toujours de 3' 56',555 en ad morenne, et de q. 8564 par heurs, on pourre facilement obtenir l'acceptation droite pour une hours que le onque à Paris, on pour le midi **moven d'un autre e**ndroit. : 15 On demende le 6 septembre l'ascension droite au midi moyen d'un lieu dont la longitude occidentale est de 3/20/3 201 Le changement heraire d'ascension, droite étent de 9", 8564, on le Protecte de 3a 45 en 31 ao - Ajoutent ces 35 à Pascengion droite 11/1/26 Doidution dure 11h 1'69 75 poer l'ascension droite demandée. 1. Avec l'ascension droite moyenne on trouve promptement le tems moyen du passage d'une étoile par le méridien.

Exemple. On demande en tems moyen l'heure du passage d'Antarès au méridien de Paris, le 6 septembre 1837?

Ascension droite apparente d'Antarès le 6 septembre (page 246).

Ascension droite moyenne du Soleil le 6 à midi.

Tems sidéral compté de midi moyen, heure appr.

\$\frac{5}{18}, \frac{33}{2723},
\$\frac{33}{2860},
\$\frac{11}{1928}, \frac{32}{23},
\$\frac{13}{280},
\$\frac{11}{280}, \frac{32}{23},
\$\frac{11}{280}, \frac{33}{23},
\$\frac{11}{280}, \frac{32}{23},
\$\frac{12}{23}, \frac{12}{23},
\$\frac{12}{23}, \fra

Si l'on ne voulait savoir qu'à 1' près l'heure du passage, pour se préparer à l'observation, il suffirait de diminuer l'heure approchée à raison de 1' pour 6^h, et l'on trouverait 5^h 17'.

On trouve de même le passage au méridien des planètes, au moyen de leur ascension droite.

L'ascension droite moyenne sert encore à trouver le tems moyen par la hauteur absolue d'une étoile.

#### Longitude vraie du Soleil à midi moyen, more suo?

Cotte longitude a été calculée pour le midi moyen de chaque jour ou sur les Tables de Delambre; mais les calculs ont été faits d'une maniles abrégée, qui, sans rien négliger, porte avec elle sa vérification et permet de renfermer, dans un tableau d'une seule page, tout ce qui concerne le Soleil pendant un mois entier, c'est-à-dire la longitude vraie, le déclinaison, l'ascension droite, le tems moyen, le lever, le coucher, le demi-diamètre, le mouvement horaire, et enfin, le logarithme du rayon vecteur.

On trouvera la longitude du Soleil pour une autre heure du jour la Paris, par cette règle: 24 heures sont à l'heure moyenne donnée compte de midi, comme la différence entre les longitudes pour le midi qui précètie et le midi qui suit l'heure donnée, est à un quatrième terme, qui, étant ajouté à la longitude pour le premier midi, donnéra la longitude du Soleil pour l'heure proposée.

Si l'on veut avoir la longitude du Soleil à une heure moyenne donnée dans un autre pays, on commencera par chercher, au moyen de la différence de longitude, l'heure qu'il est alors à Paris, et l'on suivra la règle ci-dessus.

and a some time and a surprise for the

#### SECONDE PAGE DU MOIS.

Ascension droite vraie du Soleil.

L'ascension droite vraie donnée en tems sidéral, étant convertie en degrés à raison de 15° par heure, on aura l'ascension droite du Soleil en degrés pour midi moyen. Une erreur de 1" dans la longitude donnerait. sur cette ascension droite, une erreur de + 0",996 - 0",882 cos 2 O.
On trouvera l'ascension droite vraie pour une autre heure du jour, à

Paris, par la même règle que pour la longitude.

4.3

Si l'on vent avoir l'ascension droite vraie à une heure donnée dans un autre endroit; il faudra la culculer pour l'heure que l'on compte au même instant à Paris, et que l'on obtiendra toujours par la longitude en tems de cet endroit

L'accension, droite vraie sert journellement à connaître l'état d'une horloge reglée sur le tems sidéral par l'observation du passage du Soleile au méridien. La différence entre le tems du passage observé et l'accession droite vraie du Soleil calculée pour midi vrai, indique de combien l'hory loge est en avance ou en retard sur le temps sidéral.

# Déclinaison du Soleil.

Nous avons dit (page 370) comment a été calculée la déclinaison pour le midi moyen à Paris, et (page 368) comment il faudrait la corriger si l'on supposait une obliquité différente.

On trouvera la déclinaison à une autre heure sous le méridien de Paris, en operant comme il a été explique (page 370) pour la longitude

du Soleil.

On demande la déclinaison pour Paris le 6 septembre 1837, à 3h 25'

du soir, tems moyen?

On dira: 24h sont à la variation diurne 22 27,7, comme 3h 25 est à un quatrième terme que l'on trouvera de 3 11,86. Retranchant cette diminution de déclinaison en 3ª 25' de la déclinaison 6º 26' 33",9 le 6 à midi, on aura 66 23' 22", o pour la déclinaison demandée.

Le calcul de la déclinaison dans un autre lieu, sera le même quand on aura déterminé par la différence de longitude l'heure que l'on compte à

Paris à l'instant pour lequel on veut l'oblenir.

La déclinaison du Soleil sert pour trouver la hautenr du pôle et pour avoir l'heure en mer par la hauteur observée du Soleil.

#### Tems moyen au midi vrai.

Le tems vrai ou apparent est celui qui est réglé par le mouvement vrai du Soleil; ainsi le midi vrai est l'instant où le centre du Soleil est dans le méridien. Un jour vrai est l'intervalle de tems de deux retours du Soleil au même méridien : pendant cet intervalle il passe au méridien 360 degrés de l'équateur céleste, plus un arc de cercle égal au

જારાશ કોંગ કાલોલ્ટ છે. હ

mouvement diarne du Solail en accention dutaite, Ainsi ne menutant étant inégal, lei jours vrais me penvent être éganz. Line hor loge dians réglée sur le teme meyen ne s'accorde ance le fams vrai que que que que fois dans l'année; tous les autres jours elle est en avance en en parier turd, selon que la longitude moyenne du Solail est plus petite on plus grande que son accession droîte vrais.

La commissance du rapport du tema moyen su teme veal est donn mer cessaire pour régler les pendules et les montres marines sur le mouvement moyen du Soleil; elle est indispensable pour l'usage des tables astronomiques, parce que ces tables ne pouvant être disposées que pour des tems égaux et uniformes, c'est toujours le tems moyen qu'il faut employer pour calculer le lieu d'une planète. Enfin l'équation du tems est d'une nécessité absolue dans tous les lieux où, comme à Paris, les horloges publiques sont réglées sur le tema moyen.

horloges publiques cont réglées sur le tems moyen.

Le tems moyen au midi vrai est d'un grand usage pour la couversion du tems vrai en tems moyen et réciproquement. Comme il est donné pour Paris avec son mouvement diurne, on le trouvera facilement pour le midi vrai d'un lieu dont la longitude est conque, en opérent comme à la page 370, pour la longitude du Soleil.

## Demi-diametre du Soleil.

On a mis au bas de la page le demi-diamètre du Soleil, calculé de cinq en cinq jours sur les Tables de Delambre. Dans ces Tables, on a admis le diamètre apogée de 31'31", d'après les observations faites par Lalande en 1764, avec un héliomètre d'environ six mètres.

# TROISIÈME ET CINQUIÈME PAGES DU MOIS!

## Longitude et latitude, de la Lane.

Les longitudes et les latitudes de la Lune ent été calculées pour midi et minuit, tems moyen, par les Tables de Burckhardt. On peut les conclure par interpolation pour tout autre moment, en ayant égard aux secondes différences. (Voy. page 373, le calcul de la déclinaison.) Les positions que l'on trouvera ainsi seront d'une exactitude presque égale à celle qu'on obtiendrait en calculant directement par les tables.

#### Parallame horizontale équatoriale de la Lune,

La parallaxe horizontale que l'on trouve ici pour le midi et le minuit moyen de chaque jour est calculée sur les Tables de Burckhardt. On aura la parallaxe pour une autre heure à Paris, ou dans un lieu quelconque, en suivant une règle analogue à celle qui a été donnée ci-dessus (page 370) pour le calcul de la longitude du Soleil.

Si la Terre était sphérique, la parallaxe, ou Fangle sous lequel on voit, de la Lune, le rayon de la Terre, aurait au même instant la même valeur à l'équateur et dans un lieu quelconque. Mais la Terre est un

iphticolde a plati ; la parellane diminace a vec le rispande la Respondenciale ficiente du un s'éloigne de l'équateure Suit pe la spacellate (horizontele équateure), a l'aplatissement de la Terrey la spacellate en un point dolute la titude est L, sera prompsin L

QUATRIÈME ET SIXIÈME PAGES DU MOIS
L'ascension droite et la déclinaison de la Lune serviront à calculer sa hauteur avec assez de précision pour réduire les distances à raison de la réfraction et de la parallaxe, si l'on ne peut pas observer cette hauteur à l'époque où l'on mesure des distances lunaires à la mer.  La déclinaison de la Lune est utile pour avoir la latitude géographique en mer, quand ou observe la hauteur méridienne de cet astre. Les ascensions droites pourront servir à déterminer la différence de longitude entre deux lieux où l'on aura observé un grand nombre de passages au méridien de la Lune.  L'ascension droite et la déclinaison de la Lune sont données chaque jour pour midi et minuit. On peut les obtenir par interpolation pour d'autres heures, en tenant compte des secondes différences, qui donnent lieu à une correction que l'on trouve dans une table page 310.  On demande la déclinaison de la Liune le 4 septembre 2837, à 5 du mattin, à Paris?  Déclinaison ( Différences
Déclinaison ( Différences

La différence seconde moyenne étant 4"49",5; ou trouve dans la militable page 310, vis-le-vis-5", une correction de 20",2" poun 4" et de 6",0 "pour 40". La correction totale 85", a est positive, parce que la différence seconde moyenne est négative.

#### Demi-diamètre horisontal de la Lune.

Les Tables de Burckhardt supposent le rapport, e,545 entre le diamètre de la Lune 31' 3".9 et la constante 57' de la parallaxe sous l'équateur; il a diminué de 3",5 le diamètre déterminé par Lalade, et adopté par Burg.

Le diamètre de la Lune est le même pour toutes; les latitudes, et il n'y a d'autre correction à y faire que celle qui dépend de sa vaniation en 12 heures, quand on yeut l'avoir pour une autre heure que midis en minuit.

Mais, dans le calcul des distances observées de la Lune au Scieil, aux planètes et aux étoiles, et dans celui des éclipses de Soleil, d'étoiles et de planètes, il faut avoir égard à l'augmentation du demi-diamètre horizontal de la Lune à raison de sa hauteur. Cette augmentation, qui s'élève au plus à 19", se trouve dans la plupart des tables astronomiques.

### SEPTIÈME PAGE DU MOIS.

Cette page renferme des articles du Calendrier d'une grande utilité pour le public. On y trouve principalement les levers, les couchers et les passages au méridien de la Lune et des planètes.

Le lever et le coucher des planètes ne conviennent qu'à la latitude de Paris; ils sont donnés en teus mayen. Ils serviront à reconnaître si une planète sera sur l'horizon à l'heure où quelques circonstances engagent à l'observer.

Les passages au méridien de Paris sont en tems moyen astronomique, toujours compté de midi moyen.

Le lever, et le coucher de la Lune à Paris sont calculés en temme compte de la réfraction et de la parallaxe.

On trouve dans une colonne le jour de la Lune qui répond au quantième du mois, en comptant : pour le jour de la nouvelle Lune vraie, si elle arrive avant midi; quand elle arrive après midi, c'est le lendemain qui est désigné pour le premier jour de la Lune.

Les phases de la Lune marquées au bas de la page sont exprimées en tems civil moyen au méridien de Paris.

### Passage de la Lune au méridien.

Le passage du centre de la Lune au méridien de Paris est donné en tems moyen; il est nécessaire aux astronomes qui veulent observez la Lune au méridien, et il sert encore à trouver l'houre des marées. 39 An détermine a le turne du passage de la Luce au mécidien poud un juite lieu que Paris, en faisant la proportion utivante : aé heures eu 360° sont à la différence de longitude, en tems ou en degrés, comme la différence des passages d'un jour à l'autre est à un nombre de minutes et secondes, aujon ajouters à l'heure du passage à Paris, si le lieu proposé minocidentel, ou qu'op en retranchera si le lieu est oriental, et l'on aura le tems du passage au méridien de ce lieu.

### -All dates To HUTTIEME PAGE DU MOIS.

in Les longitudes et les latitudes héliocentriques et géocentriques des planètes sont données au midi moyen de Paris pour chaque jour indiqué.

Les ascentions droites, en tems, des planètes, sont aussi pour midi mayen. Elles sont très commodes pour les astronomes qui ont leurs pendales réglées sur le tems sidéral, et qui veulent connaître les passages des planètes au méridien. Les ascensions droites les dispensent du calcul qu'ils seraient obligés de faire pour les conclure des passages en tems moyen qu'on trouve sur la septième page.

jour déclinaison est aussi donnée pour le midi moyen à Paris de chaque jour indique; ou la réduira au tems du passage par le méridien, ou à toute souve heure, par le moyen du changement d'un jour à l'autre.

On peut aussi déterminer la latitude à la mer par l'observation de la hauteur méridienne de Salurne, de Jupiter ou de Mars, lorsque ces planètes passent au méridien pendant la nuit; et mieux encore quand elles y passent dans le crépuscule du matin ou du soir, qui permet de bien distinguer l'herizon de la mer.

### ob obutrusi ad a sp. trong para est de la MOISa de la restama NEUNIEME PAGE DU MOISa

to produce the contract of the continues of

Le tems que le demi-diamètre du Soleil met à passer par le méridien est méridien aux astronomes, lorsqu'ils observent au méridies le bord de cet astre, et qu'ils veulent en conclure le midit il est donné en tems sidéral et en tems moyen, pour les dispenser de toute réduction.

Le mouvement horaire du Soleil en longitude et le logarithme de sa distance à la Terre, sont mécassaires dans plusieurs calcule astronomiques, pour les éclipses, pour les comètes, les planètes, pour les oppositions des planètes.

Le lieu du nœud de la Lune sert à calculer la mutation des étoiles fixes et des planètes.

### Eclipses des Satellites de Jupiter.

Les éclipses des satellites de Jupiter sont calculées par les dernières Tables que Delambre à faites d'après la théorie de Laplace.

Les observations de ces éclipses offrent aux voyageurs des moyens fréquens de déterminer les longitudes; elles sont très faciles à faire, surtout

à terre. Une pendule ou un garde-tems, une lumitée acnomatique d'environ: un mètre, ou un télescope de 6 à 7 décimitées des touteurs quart-de-cercle ou tout autre instrument propre à prendre des hauteurs absolues pour tranvers le tems, l'aufifisent pour faire sur les satellites des observations utiles.

Afin de reconnaître aisément la place du satellite deux en se fire pose d'observer l'immersion ou l'émersion, il suffit de fine les semandres suivantes:

1°. Avant l'opposition, c'est-à-dire pendant tout le tems que Jupiter passe au méridien le matin, l'ombre est située à l'occident de cette planète, et les immersions ou les émersions se font de ce caté.

2°. Après l'opposition de Jupiter, lorsqu'il passe au méridien avant minuit, c'est toujours à l'orient de la planète que sont les satellites qui doivent entrer dans l'ombre, ou qui doivent en sortir.

Si l'on se sert d'une lunette qui renverse les objets, les apparences seront contraires.

5°. Avant l'opposition, on ne peat voir que les immersions du premier satellite; et après l'opposition, il n'y a que les émersions qui puissent être observées: c'est en général la même chose pour le second satellite. Il arrive cependant qu'on peut observer l'immersion et l'émersion, lorsque Jupiter est en quadrature. Délambre a donné, dans le volume de 1703, des Tables pour déterminer ces circonstances.

Toutes les éclipses des satellites sont indiquées en tems moyen astronomique compté de midi; on a marqué d'un asterisque celles qui sont
visibles à Paris. Lorsque l'on sera sous un autre méridien, on ajoutera
aux tems marqués des éclipses la différence des langitudes, réduite en
tems, si l'on est à l'orient de Paris, ou on l'en retranchera si l'on est
à l'occident, et l'on aura le tems pour le lieu on l'éclipse doit s'observer; ensuite, si ce tems tombe dans la nuit, on verra si Jupiter
doit être sur l'horizon, au moyen de son levue et de son éculeller.

### DIRIÈME PAGE DU MOIS

### Configuration des Satellites de Jupiter:"

Les configurations des satellites sont indiquées pour des linere qui est marquée au haut de la page; con configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations configurations de la ligne, et les chiffres de chiffres de la ligne, et les chiffres de la sent dans la partie supérieure de leurs caroles, et la plus éloisquée de la Terre, lorsqu'ils sont à gauche ou à l'occident, et qu'ils roche de la Terre, lorsqu'ils sont dans la partie inférieure, ou la plus proche de la Terre, lorsqu'ils sont dans la partie inférieure, ou la plus proche de la Terre, lorsqu'ils sont du même côté et qu'ils s'éloignent de Jupiter; c'est le contraire lorsqu'ils sont à droite ou à l'orient. Le zéro, accompagné d'un chiffre, signifie qu'un satellite est sur le disque de Ju-

piter; et le gree point noir, accompagné aussi d'un chiffre, indique cul'un satellite est dans l'ombre, ou bien derrière le disque de Juniter.

Rour déterminer ces configurations, on s'est servi des tables calculées par Delambre, et qui donnent facilement les positions des satellites, soit dans le sens de l'équateur de Jupiter, soit dans le sens de la latitude: ees tables serviraient également à calculer les passages des satellites sur le disque de Jupiter. Ces tables se trouvent dans le volume de 1808.

#### ONZIÈME A DIX-NEUVIÈME PAGES DU MOIS.

Distance du centre de la Lune au Soleil et aux Étoiles.

Les distances vraies orientales et occidentales de la Lune au Soleil et aux étoiles, sont données pour le tems moyen de Paris de 3 heures en 3 heures en comptant oh à midi moyen. On a mis à côté les différences des distances dans cet intervalle, pour faciliter le calcul des interpolitions. Pour en montrer l'usage, supposons qu'on demande l'heure qu'il était à Paris le 16 septembre 1837, à l'instant où la distance orientale vraie d'Aldébaran était de 43° 2′ 25"?

Cette distance tombe page 164 entre les distances du 16 à 6h et à 0h du soir, qui different de 1º 44' 13", et elle est de 1º17 58" plus petite que celle

de 6^t. On fera la proportion

Les distançes lunaires que l'on observe sont affectées des effets de la parallaxe et de la réfraction; il faut les en dégager pour avoir les distances vraies et pouvoir les comparer aux distances que l'on trouve dans ee livre.

On pont employer la méthode de Borda, dont le calcul est simple et rigeureux, pour passer de la distance apparente observée à la distance vraie. On trouve, pages 308 et 309, une TARLE des différences logarithmiques, construite par Burckhardt, non-seulement pour en faciliter l'unge, mais principalement pour procurer plus d'exactitude, car le conflicient que la table donne ne se trouve pas avec précision, en employant les Tables de réfraction et les Tables trigonométriques

On a cheervé une distance apparente de 83º 57' 33" entre le Soleil et la Lune, dont les hanteurs apparentes étaient 48° 27' 30°, et 27° 34', le baremètre étant à at, 76a, et le thermomètre centigrade à + 26°,3. On de-

mande la distance vreis?

Avec la hauteur apparente du Soleil, la Table première donne 1089; il fant sjouter treis parties pour le baromètre qui était à om762, au lieu de on 96, et ster 82 pour le thermomètre, qui était à 26°,3 au lieu de 10. La correction totale sera donc 18 parties à retrancher de 1080, et l'on aura 1011 pour le nombre de la Table.

### PHÉNOMÈNES ET OBSERVATIONS.

Pages 224, 225, 226, 227, 228 et 229.

On indique pour tous les jours de chaque mois, en tems moyen astronomique compté de midi, les observations les plus intéressantes. Les occultations des planètes par la Lune, et celles des étoiles qui ne sont pas audessous de la quatrième grandeur, sont calculées pour Paris : on a soin de donner la différence de latitude apparente entre le centre de la Lune et l'étoile au moment de l'émersion; car, quand on ne sait pas à très peu près à quel point du disque l'étoile doit sortir, on manque très souvent l'observation de l'émersion. Mais, si l'on a une machine parallactique, et qu'avant l'immersion, on ait mis l'étoile près du fit parallèle à l'équateur, on est sûr, à l'émersion, de la retrouver près du même fil.

On donne aussi le tems moyen compté de midi à Paris, de la conjonetion des étoiles qui peuvent être éclipsées par la Lune dans quelque lieu que ce soit du globe. Les occultations d'étoiles par la Lune étant les phénomènes les plus propres pour déterminer avec précision les longitudes géographiques, les voyageurs ne doivent pas négliger de les observer; les conjonctions qu'on indique ici serviront à les gaider pour prévoir les occultations qui pourront avoir lieu dans les pays où its se

trouveront.

Les éclipses de Soleil fournissent aussi un des moyens les plus exacts

pour déterminer les longitudes.

L'observation des éclipses de Lune n'est pas susceptible de la même précision, parce que les bords de l'ombre de la Terre sont ai diffus, si mal terminés, qu'il en résulte une grande incertitude sur les vrais instans des phases. On ne devra cependant pas négliger ces observations lorsqu'elles se présenteront; mais on obtiendra plus d'exactitude dans les résultats, si l'on observe les immersions et les émersions des principales taches de la Lune, et si on les compare aux observations des mêmes taches qui auront été faites sous un méridien connu.

### 21 Positions apparentes de 67 étoiles principales.

Pages 230 à 252.

21 On donne pendant l'année 1837 les ascessions droites et les déclinaisons apparentes pour 66 étoiles principales, de 10 jours en 10 jours, et Mour la polaire de 3 jours en 3 jours. On donne aussi la position moyenne de chaque étoile le 1et janvier 1837.

#### DISTANCES DE LA LUNE AUX PLANETES.

Pages 253 à 302

Les distances vraies du centre de la Lune au centre des quatre planètes Vénus, Mars, Jupiter et Saturne, sont données de 3 heures en 3 heures nour le tems moyen de Paris. On obtiendra les heures corresendantes à des distances intermédiaires par interpolation, en opérant comme pour les distances au Soleil et aux étoiles. (Voy. page 377.)

Ces distances ne sont pas rangées par mois; on trouve d'abord les distances de la Lane à Vénus pendant toute l'année : on les trouve ensuite

pour Mars, pour Jupiter, et enfin, pour Saturne.

On donne à la page 303 la parallaxe horizontale et le demi-diamètre de ces quatre planètes à différentes époques de l'année, et à la page 304, <del>le Tableau</del> des grandes marées de 1837.

A la suite de tout ce qui compose cette éphéméride, viennent diffé-

rentes espèces de Tables pour en faciliter l'usage.

Les Tables de réfraction, pages 305 à 306; les Tables pour le calcul des distances lunaires, pages 308 et 300; une Table pour la correction des secondes différences dans les interpolations, page 310; plusieurs Taliles de conversion pour le tems et les degrés, pages 311 à 315; une Table de la parallaxe de hauteur du Soleil, page 316; un Catalogue des positions moyennes au 1er janvier 1830, de 100 étoiles de 2º à 3º grandeur, pages 317 et 318; on trouve enfin, page 319, la Table des positions géographiques.

### LA PRÉCESSION DES ÉQUINOXES,

Dans l'hypothèse d'une très petite obliquité de l'écliptique, et spécialement d'une vitesse initiale de rotation égale à zéro.

PAR M. POISSON.

(Lu à l'Académie, le 21 juillet 1834.)

La solution ordinaire du problème de la précession des équinoxes conduit à une valeur de la précession annuelle qui est en raison inverse de la vitesse du mouvement diurne. Il en résulte que si cette vitesse devenait double, triple, quadruple, etc., celle des équinoxes se réduirait à moitié, au tiers, au quart, etc., et deviendrait insensible pour un mouvement de rotation suffisamment rapide. Mais il ne s'ensuit pas, réciproquement, que si la vitesse du mouvement diurne devenait extrêmement petite, le mouvement des équinoxes s'accélérerait indéfiniment, et deviendrait extrêmement grand. En effet, la solution ordinaire du problème suppose que la vitesse de la Terre, parallèlement à l'équateur, ne soit ni zéro, ni très petite par rapport à celle de chacun des astres qui agissent sur le sphéroïde, et l'expression que l'on obtient pour la précession annuelle n'est plus applicable dès que cette condition a cessé d'être remplie. La valeur infinie que prend cette formule, dans le cas d'un mouvement diurne égal à zéro, indique seulement que la quantité de la précession est une fonction de la vitesse de rotation, qui n'a pas la même forme pour une valeur quelconque de la variable, et pour une valeur très petite : en sorte que le problème doit être résolu différemment dans les deux cas. Cette quantité est aussi une fonction de la différence des momens d'inertie de la Terre; et, sous ce rapport, la valeur approchée à lasuelle on s'arrête, est le premier terme d'une série ordonnée suivant les puissances de cette différence, ou de son rapport à l'un de ces momens. Or.

dans le cas général, la série procède suivant les puissances entières de ce rapport, auquel son premier terme est proportionnel; mais dans le cas d'une très petite vitesse de rotation, la série est ordonnée suivant les puissances fractionnaires du même rapport, et le premier terme est seulement proportionnel à sa racine carrée, comme on le verra dans ce mémoire. Le passage d'une forme de développement à l'autre est indiqué iei par des valeurs infinies des coefficiens, ainsi que cela arrive, par exemple, dans les cas où le théorème de Taylor se trouve en défaut.

Quoique le cas d'une très petite vitesse de rotation n'ait pas lieu dans la nature, j'ai pensé qu'il ne serait pas inutile de déterminer les mouvemens de l'équateur, en latitude et en longitude, dans l'hypothèse d'une vitesse de rotation primitivement égale à séro, et qui demeure constamment très petite. Mais cette question n'ayant pas d'application directe dont les données soient fournies par l'observation, j'ai supposé, pour la simplifier, que l'obliquité de l'écliptique soit aussi constamment très petite; ce qui a permis de ramener les équations différentielles du problème à la forme linéaire, par la transformation que Lagrange a employée le premier dans son second mémoire sur la Libration de La, Lune.

1. Pour abréger, je prends dans le livre V de la Mécanique cèleste les six équations différentielles du mouvement de la Terre autour de son centre de gravité, regardé comme un point fixe autour duquel le Soleil est en mouvement. L'action de cet astre est la seule dont on tiendra compte; on fera abstraction des inégalités de son mouvement et des déplacemens de l'écliptique.

Trois de ces équations seront d'abord celles-ci :

$$\frac{dp}{dt} + \frac{B - A}{C}qr = \frac{3L(B - A)}{2l^5C} [(Y^5\cos^4\theta - X^5)\sin 2\theta + 2XY\cos\theta\cos 2\theta],$$

$$\frac{dq}{dt} + \frac{C - B}{A}rp = \frac{3L(C - B)}{l^5A}(Y\cos\theta\cos\phi - X\sin\phi)Y\sin\theta,$$

$$\frac{dr}{dt} + \frac{A - C}{B}pq = \frac{BL(A - C)}{l^5B}(Y\cos\theta\sin\phi + X\cos\phi)Y\sin\theta,$$
(3)

qui résultent des équations (G) du livre cité (*), en y faisant Z = 0, et y

^(*) Tome II, page 309.

mettant la lettre I au lieu de r,. Les trois autres équations seront

$$d\phi - \cos t d\psi = p dt,$$

$$\sin t \sin \phi d\psi - \cos \phi dt = q dt,$$

$$\sin t \cos \phi d\psi + \sin \phi dt = r dt;$$
(2)

A, B, C, désignant les trois momens d'inertie principaux de la Terre. C est le plus grand, et se rapporte, en conséquence, à la ligne des pôles; le plan des deux autres axes auxquels répondent A et B est l'équateur.

Au bout du temps quelconque t, les trois inconnues p, q, r, sont les composantes de la vitesse angulaire de rotation : p se rapporte à l'axe des pôles, et exprime, par conséquent, la vitesse du mouvement diurne; q et r répondent aux deux axes compris dans le plan de l'équateur. Il en résulte que si l'on appelle p cette vitesse angulaire, ou la résultante de p, q, r, on aura

$$\bullet = \sqrt{p^* + q^* + r^2},$$

et les trois rapports  $\frac{p}{\omega}$ ,  $\frac{q}{\omega}$ ,  $\frac{r}{\omega}$ , seront les cosinus des angles que l'axe instantant de rotation fait avec les trois axes principaux.

Au même instant,  $\psi$ ,  $\varphi$ ,  $\theta$ , sont les trois angles d'où dépend la position du sphéroïde, c'est-à-dire, les trois inconnues définitives du problème, qu'il s'agira de déterminer en fonctions de t. L'angle  $\psi$  est celui que fait l'intersection de l'équateur et du plan de l'écliptique, avec une ligne fixe menée dans ce plan par le centre de la Terre; on suppose qu'il se rapporte à l'équinoxe du printemps, et qu'il est compté, à partir de la ligne fixe, en sens contraire du mouvement du Soleil. L'angle  $\varphi$  est compris entre cette intersection et l'axe auquel répondent le moment  $\Delta$  et la vitesse q; il est compté sur le plan mobile de l'équateur, à partir de l'équinoxe du printemps et dans le sens du mouvement du Soleil. L'angle  $\theta$  est l'inclinaison de l'équateur sur le plan de l'écliptique.

Les deux quantités X et Y sont les coordonnées variables du centre du Soleil; la première est comptée sur la ligne qui va du centre de la Terre à l'équinoxe du printemps, et la seconde sur un axe qui fait avec cette droite un angle de 90°, compté dans le sens du mouvement du Soleil, à partir de cette même droite. Leurs valeurs seront

$$X = l \cos(mt + \psi)$$
,  $Y = l \sin(mt + \psi)$ ,

en désignant par l la distance moyenne du Soleil à la Terre et par mt le moyen mouvement de cet astre, et en supposant que la droite d'où l'on compte l'angle  $\downarrow$  soit celle qui va du centre de la Terre à celui du Soleil quand t == 0, de sorte que  $mt + \downarrow$  exprime la loagitude moyenne du Soleil à un instant quelconque, comptée à partir de l'équinoxe mobile du printemps.

On représente aussi par L la masse du Soleil, ou plutôt la mersure de son pouvoir attractif à l'unité de distance. Il en résulte que, l'on a

$$L = m^2 l^3$$
.

Toutefois, lorsque le Soleil sera supposé immobile, c'est-à-dire, lorsque la force attractive émanera d'un centre fixe, la constante m sera nulle, et il faudra mesurer autrement l'intensité de cette force; ce qui ret viendra à faire m = 0 dans les valeurs de X et Y seulement, et à considérer m dans la valeur de L comme une vitesse angulaire telle que  $m^2l^3$  soit la force donnée.

2. Je supposerai, comme je l'ai dit plus haut, que l'obliquité de l'écliptique soit constamment très petite; je négligerai, en conséquence, les puissances de supérieures à la première, et je mettrai partout set l'unité à la place de sin set cos s. Si l'analyse fondée sur cette hypothèse donne effectivement une valeur de sen sonction de t, qui reste toujours très petite, cette valeur sera admissible, et d'autant plus approchée qu'elle sera un plus petit angle. Si, au contraire, on trouve pour sune valeur croissante et qui cesse d'être très petite au boat d'un certain temps, quoiqu'elle le soit à l'origine, il sautre la rejeter et recourir à d'autres moyens pour déterminer s à un instant quelconque.

Pour simplifier la question, je supposerai aussi que l'on ait B=A; ce qui réduira la première équation (1) à dp=0. La vitesse p du mouvement diurne sera donc invariable; je la représenterai par une constante donnée n, qui pourra être zéro, et qui sera positive ou négative, selon que le mouvement diurne aura lieu dans le sens ou en sent contraire du mouvement du Soleil.

La première équation (2) deviendra

$$d\phi - d\psi = nd\iota$$
.

Toutes les droites menées par le centre de la Terre dans le plan de l'équateur, étant des axes principaux, à cause de B = A, on pourre prendre telle droite que l'on vondre peur l'axe auquel répond l'angle el

Fe surpposerai que cette droite seit celle dont la projection sur le plan de Fécli ptique, coincidait, à l'époque d'où l'on compte le temps t, avec la ligne fixe d'où l'en compte l'angle \(\psi\), de sorte que l'on ait \(\rho\) == \(\psi\) ; il en résultera, à un instant quelconque,

$$\psi = \varphi - nt \; ; \qquad (3)$$

es qui fera connaître l'inconnue 4 d'où dépend la précession des équinomes, lorsque l'angle quara été déterminé.

En mettant  $d\phi - ndt$  au lieu de  $d \downarrow$  dans les deux dernières équations (2), et faisant ensuite

$$\theta \sin \varphi = s$$
,  $\theta \cos \varphi = s'$ ,

elles prendront la forme ;

$$q = -\frac{ds'}{dt} - ns,$$

$$r = \frac{ds}{dt} - ns'.$$
(4)

En mettant aussi  $\varphi$  — nt au lieu de  $\psi$ , dans les valeurs de X et Y, on en conclut

$$Y \cos \varphi - X \sin \varphi = l \sin (m - n)t$$
,

$$Y\sin\phi + X\cos\phi = l\cos(m-n)t,$$

$$\theta \mathbf{Y} = ls' \sin(m-n)t + ls \cos(m-n)t;$$

du moyen de quoi et des valeurs précédentes de q et r, les deux dernières équations (1) déviendront

$$\frac{d^3s'}{dt'} + \left(z - \frac{C - A}{A}\right)n\frac{ds}{dt} + \frac{C - A}{A}\left(n^3 + \frac{3}{2}m^3\right)s' = \frac{3(C - A)m^3}{2A}\left[s'\cos a(ms - n)z - s\sin a(ms - n)z\right],$$

$$\frac{d^3s}{dt^2} - \left(1 - \frac{C - A}{A}\right)n\frac{ds'}{dt} + \frac{C - A}{A}\left(n^2 + \frac{3}{2}m^2\right)s = \frac{3(C - A)m^2}{2A}\left[s\cos 2(m - n)t + s'\sin 2(m - n)t\right]d$$

Dans le cas particulier de m=n, tous les coefficiens de ces deux équations linéaires seront constant, par conséquent, ou pourra alors intégrer ces deux équations sous forme finie, quelle que soit la différence G. A. Dans tout autre cas , les coefficiens de s et s' dans les seconds

membres ne sont plus constans; mais, à cause de leur facteur  $\frac{C-A}{A}$ , que nous supposerons une très petite fraction, on pourra toujours intégrer ces équations par la méthode des approximations successives, et déterminer les valeurs de s et s'aussi exactement que l'en voudra.

Les intégrales complètes de ces équations (5) rensermeront quatre constantes arbitraires, que l'on déterminera d'après la position et la vitesse du mobile à l'origine du mouvement. Pour cela, je représenterai par C et  $\gamma$  les valeurs données qu'avaient les angles L et  $\theta$  à cette époque, ce qui fixera la position initiale du sphéroïde; et je désignerai, en même tems, par a et b les valeurs aussi données des composantes q et r de sa vitesse de rotation, lesquelles valeurs, jointes à la troisième composante p=n, détermineront, en grandeur et en direction, cette vitesse de rotation à l'origine du mouvement. En comptant le tems t à partir de cette origine, observant qu'on a, par hypothèse,  $\phi=\psi$  quand t=0, et ayant égard aux expressions précédentes de s, s', q, r, nous aurons

$$s = \gamma \sin \zeta, \quad s' = \gamma \cos \zeta,$$

$$\frac{ds'}{dt} + ns = -a, \quad \frac{ds}{dt} - ns' = b,$$
(6)

pour cette valeur particulière t = 0; équations qui suffiront pour la détermination des quatre constantes arbitraires.

On pourra faire telle supposition que l'on voudra sur les vitesses a et b; et, selon les valeurs qu'on leur attribuera, il en résultera différens mouvemens pour l'équateur et pour la ligne des équinoxes; mais afin de simplifier ces mouvemens, et pour qu'ils ne soient dus qu'à l'action du Soleil sur le sphéroïde terrestre, combinée avec la vitesse de rotation parallèle à l'équateur, quand celle-ei n'est pas nulle, nous supposerons, dans tous les exemples suivans, les constantes a et b égales à séro.

3. Examinons spécialement le cas où la troisième composante n de la vitesse initiale est aussi nulle, de sorte que tous les points de la Terre soient en repos à l'époque d'où l'on compte le tems t, et que son mouvement soit produit uniquement par l'action du Soleil.

En faisant donc n=0, a=0, b=0, les équations (6) relatives à t=0 se réduiront à

$$s = \gamma \sin \theta$$
,  $s' = \gamma \cos \theta$ ,  $\frac{ds}{dt} = 0$ ,  $\frac{ds'}{dt} = 0$ . (7)

Dans le:cas de n = 0, on aura, d'après l'équation (3),

un instant quelconque, et les équations (5) deviendront servites aurant

$$\frac{d^2s}{dt^2} + \alpha^2 m^2 s = -\alpha^2 m^2 (s \cos 2mt + s' \sin 2mt),$$

$$\frac{d^2s'}{dt^2} + \alpha^2 m^2 s' = \alpha^2 m^2 (s' \cos 2mt - s \sin 2mt),$$
(8)

où l'on a fait, pour abréger,

$$\frac{3(C-A)}{2A} = \alpha^2.$$

Les angles  $\varphi$  et  $\psi$  étant constamment égaux, il s'ensuit que le rayon le l'équateur auquel répond l'angle  $\varphi$ , et dont la projection sur le plan de l'écliptique coïncidait avec le rayon vecteur du Soleil à l'origine du nouvement, demeurera constamment dans un même plan perpendiculaire à celui de l'écliptique. A cause de n=0, la vitesse de rotation sera toujours nulle parallèlement au plan de l'équateur, et l'axe instantané de rotation restera constamment dans ce plan. Si donc on appelle  $\zeta$  l'angle que fait cet axe avec le rayon de l'équateur correspondant à l'angle  $\varphi$ , on aura (n° 1)

$$= \cos \zeta = q$$
,  $= \sin \zeta = r$ ,  $= -1$ 

pu bien, en vertu des équations (4),

$$\cos \zeta = -\frac{ds'}{dt}, \quad \alpha \sin \zeta = \frac{ds}{dt}. \quad (9)$$

Ainsi, la solution du problème, d'est-à-dire, la détermination complète de la position et de la rotation du mobile à un instant quelconque, ne dépend que de la détermination des deux inconnues set s'en fonctions du temps, au moyen des équations (7) et (8).

4. Pour intégrer les équations (3), je néglige d'abord leurs seconds membres, et je représente par z et z' ce que deviennent s et s' dans cette première approximation, de sorte qu'on ait

$$\frac{d^3x}{dt^3} + a^3m^3x = 0,$$

$$\frac{d^3x'}{dt^3} + a^3m^3x' = 0.$$

Les intégrales complètes de ces deux équations seront

$$x = D \sin amt + E \cos amt,$$
  
 $x' = D' \sin amt + E' \cos amt;$ 

D, E, D', E', étant les quatre constantes arbitraires. Je fais ensuite

$$s = x + y$$
,  $s' = x' + y'$ ;

puis je substitue ces valeurs dans les premiers membres des équations (8), et seulement x et x' au lieu de s et s' dans leurs seconds membres; d'où il résulte

$$\frac{d^2y}{dt^2} + a^2m^2y = -a^2m^2(x\cos 2mt + x'\sin 2mt),$$

$$\frac{d^2y'}{dt^2} + a^2m^2y' = a^2m^2(x'\cos 2mt - x\sin 2mt).$$

Les expressions complètes de y et y' tirées de ces deux équations renfermeront des parties semblables aux valeurs de x et x', dont on pourra faire abstraction. Pour déterminer ensuite les valeurs approchées de y et y', on négligera les termes  $a^am^ay$  et  $a^am^ay'$  des premiera membres, et l'on intégrera les seconds membres en y regardant x et x': comme des constantes, c'est-à-dire, en négligeant leurs variations provenant de cos amt et sin amt, par rapport à celles de cos amt et sin amt. De catte manière, on aura

$$y = \frac{\alpha^{3}}{4} x \cos 2mt + \frac{\alpha^{3}}{4} x' \sin 2mt,$$
  
$$y' = -\frac{\alpha^{3}}{4} x' \cos 2mt + \frac{\alpha^{3}}{4} x \sin 2mt.$$

Par conséquent, les valeurs entières de s et s' seront

$$s = (D \sin amt + E \cos amt) \left(1 + \frac{a^2}{4} \cos 2mt\right)$$

$$+ \frac{a^2}{4} (D' \sin amt + E' \cos amt) \sin 2mt,$$

$$s' = (D' \sin amt + E' \cos amt) \left(1 - \frac{a^2}{4} \cos 2mt\right)$$

$$+ \frac{a^4}{4} (D \sin amt + E \cos amt) \sin 2mt.$$

On déterminera sans difficulté les quatre constantes D; E, D', E',

qu'elles contiennent, au meyen des quatre équations (7) relatives à :==0; après quoi, si nous faisons, pour abréger,

$$\gamma \sin \theta \cos amt - \frac{1}{4} a\gamma \cos \theta \sin amt = T$$
,  $\gamma \cos \theta \cos amt - \frac{1}{4} a\gamma \sin \theta \sin amt = T'$ ,

nous aurons

ことである。 人人にの Te かなかばる

!

$$s = T\left(1 - \frac{a^2}{4} + \frac{a^3}{4}\cos 2mt\right) + \frac{a^3}{4}T'\sin 2mt, s' = T'\left(1 + \frac{a^3}{4} - \frac{a^3}{4}\cos 2mt\right) + \frac{a^3}{4}T\sin 2mt.$$
 (10)

Pour l'objet qu'on se propose dans ce mémoire, on pourrait généralement borner l'approximation à ces valeurs de s et s', qui satisfont aux équations (7) rigoureusement, et aux équations (8) en négligeant les les termes multipliés par le cube de « en dehors des sinus et cosinus. Toutefois, afin qu'il ne reste aucun doute sur la forme de ces quantités, et parce que l'approximation suivante exige une attention particulière, il sera bon d'en effectuer ici tous les calculs.

5. Pajoute donc aux formules (10) de nouvelles inconnues z et z', qui seront de très petites quantités par rapport aux valeurs de y et y données dans la seconde approximation, et qu'on négligera dans les seconds membres des équations (8), conformément à la méthode des approximations successives. Pobserve, de plus, que la substitution des formules (10) dans ces seconds membres, donnera naissance à des termes indépendans de cos 2mt et sin 2mt, et de la forme H cos amt; H étant un coefficient constant. Or, quand une équation dont le premier membre est  $\frac{d^3z}{dt^3} + s^2m^2z$  ou  $\frac{d^3z'}{dt^3} + s^2m^2z'$ , renferme dans son second membre un terme tel que H cos amt ou H sin amt, son intégrale contient, à raison de ce terme, la variable t en dehors des sinus et cosinus. Il en résulterait que les valeurs de z et z' croîtraient indéfiniment avec le tems, quoique les valeurs exactes de s et s' puissent être périodiques; ce qui proviendrait du développement, suivant les puissances de t. d'un ou de plusieurs termes périodiques contenus dans ces valeurs exactes, et mettrait en désaut la méthode d'approximation. Cette difficulté s'est présentée, comme on sait, dans les premières applications que l'on a faites de l'analyse à la mécanique céleste, et elle a été l'occasion de méthodes très ingénienses, que les géomètres ont imaginées pour la faire disparaître. Pour cela, il suffira, dans la question qui nous occupe, de mettre » + p à la place de « dans les sinus et cosinus de «mt que renferment les formules (10); p étant une constante très petite par rapport à s', dont on disposera ensuite pour rendre nuls les coefficiens des termes indépendans de cos 2mt et sin 2mt dans les équations qui serviront à déterminer s et s'.

Cela étant, je fais, pour abréger,

$$\gamma \sin 6 \cos (a+p)mt - \frac{1}{3}(a-p)\gamma \cos 6 \sin (a+p)mt = P,$$
  
 $\gamma \cos 6 \cos (a+p)mt - \frac{1}{3}(a-p)\gamma \sin 6 \sin (a+p)mt = P';$ 

je substitue ces quantités P et P' à la place de T et T' dans les formules (10), et je prends ensuite

$$s = P\left(1 - \frac{a^{a}}{4} + \frac{a^{a}}{4}\cos 2mt\right) + \frac{a^{a}}{4}P'\sin 2mt + z,$$
  
$$s' = P'\left(1 + \frac{a^{a}}{4} - \frac{a^{a}}{4}\cos 2mt\right) + \frac{a^{a}}{4}P\sin 2mt + z'.$$

J'ai mis  $\alpha - p$  au lieu de  $\alpha$  dans les coefficiens des seconds termes de P et P', afin que les parties de s et s' indépendantes de z et z' satisfassent, à très peu près, aux deux dernières équations (7); et comme elles satisfont toujours rigoureusement aux deux premières, il faudra que les nouvelles inconnues z et z' soient telles que l'on ait

$$s = 0$$
,  $z' = 0$ ,  $\frac{ds}{dt} = 0$ ,  $\frac{dz'}{dt} = 0$ , (11)

quand, t = 0.

En substituant ces dernières valeurs de s et s' dans les équations (8), négligeant s'et s' dans leurs seconds membres, observant qu'on a

$$\frac{d^{1}P}{dt^{2}} = -(a+p)^{1}m^{4}P, \quad \frac{d^{1}P'}{dt^{2}} = -(a+p)^{2}m^{4}P',$$

et réduisant, il vient

$$\frac{d^{2}z}{dt^{2}} + a^{2}m^{2}z - \frac{a^{2}}{4}(2ap + p^{2})m^{2}(P\cos 2mt + P'\sin 2mt) \\
-(2ap + p^{2})\left(1 - \frac{a^{2}}{4}\right)m^{2}P - a^{2}m^{2}\left(\frac{dP}{mdt}\sin 2mt - \frac{dP'}{mdt}\cos 2mt\right) \\
= \frac{a^{4}}{4}m^{2}(P\cos 2mt - P'\sin 2mt) - \frac{a^{4}}{4}m^{2}P, \\
\frac{d^{2}z'}{dt^{2}} + a^{2}m^{2}z' + \frac{a^{2}}{4}(2ap + p^{2})m^{2}(P'\cos 2mt - P\sin 2mt) \\
-(2ap + p^{2})\left(1 + \frac{a^{2}}{4}\right)m^{2}P' + a^{2}m^{2}\left(\frac{dP'}{mdt}\sin 2mt + \frac{dP}{mdt}\cos 2mt\right) \\
= \frac{a^{4}}{4}m^{2}(P'\cos 2mt + P\sin 2mt) - \frac{a^{4}}{4}m^{2}P'.$$

Les valeurs de z et z' qui résulteront de cette troisième approximation auront pour facteurs des puissances de « supérieures à la seconde ; les termes négligés dans les seconds membres de ces équations dépendraient donc des cinquièmes puissances de «; par conséquent, dans les calculs suivans, tous les termes dépendans des puissances de « supérieures à la quatrième seraient incomplets, et devront être négligés. Or, on sera disparaître les termes connus qui ne contiennent pas cos 2mt ou sin 2mt dans ces deux dernières équations, en prenant

$$(2ap + p^s) \left(1 + \frac{a^2}{4}\right) = \frac{a^4}{4};$$

d'où l'on tire, d'après ce qu'on vient de dire,

$$p=\frac{a^3}{8};$$

et, de cette manière, ces équations se réduiront à

$$\frac{d^2z}{dt^2} + a^2m^2z = a^2m \left(\frac{dP}{dt}\sin 2mt - \frac{dP'}{dt}\cos 2mt\right) + \frac{a^4m^4}{4} (P\cos 2mt - P'\sin 2mt),$$

$$\frac{d^2z'}{dt^2} + a^2m^2z' = -a^2m \left(\frac{dP'}{dt}\sin 2mt + \frac{dP}{dt}\cos 2mt\right) + \frac{a^4m^4}{4} (P'\cos 2mt + P\sin 2mt).$$

En les intégrant et déterminant les quatre constantes arbitraires au moyen des équations (11) relatives à t = 0, on trouve, au même degré d'approximation,

$$z = -\frac{a^2}{4m} \left( \frac{dP}{dt} \sin 2mt - \frac{dP'}{dt} \cos 2mt \right)$$

$$+\frac{a^4}{16} (3P \cos 2mt + 5P' \sin 2mt)$$

$$-\frac{5a^3}{8} \gamma \cos 6 \sin (a + p) mt$$

$$-\frac{a^4}{16} \gamma \sin 6 \cos (a + p) mt,$$

$$z' = \frac{a^3}{4m} \left( \frac{d^3 P'}{dt} \sin 2mt + \frac{d^3 P}{dt} \cos 2mt \right),$$

$$-\frac{a^4}{16} (5P' \cos 2mt - 3P \sin 2mt)$$

$$+\frac{a^3}{8} \gamma \sin \zeta \sin (a + p) mt$$

$$+\frac{7a^4}{16} \gamma \cos \zeta \cos (a + p) mt;$$

et, en effet, en ayant égard aux valeurs de  $\frac{d^3P}{dt^n}$  et  $\frac{d^3P'}{dt^n}$ , il est facile de vérifier que ces expressions de z et z' satisfont aux deux équations différentielles, quand on néglige les puissances de supérieures à la quatrième, et qu'elles remplissent aussi les conditions exprimées par les équations (11).

Les expressions de s et s' qui résultent des trois approximations successives, et auxquelles nous nous bornerons, seront donc finalement

$$s = P \left[ 1 - \frac{a^2}{4} + \left( \frac{a^2}{4} + \frac{3a^4}{16} \right) \cos 2mt \right] + \left( \frac{a^2}{4} + \frac{5x^4}{16} \right) P' \sin 2mt$$

$$- \frac{a^2}{4m} \left( \frac{dP}{dt} \sin 2mt - \frac{dP'}{dt} \cos 2mt \right) - \frac{a^3}{16} Q,$$

$$s' = P \left[ 1 + \frac{a^2}{4} - \left( \frac{a^2}{4} + \frac{5a^4}{16} \right) \cos 2mt \right] + \left( \frac{a^2}{4} + \frac{3a^4}{16} \right) P \sin 2mt$$

$$+ \frac{a^2}{4m} \left( \frac{dP'}{dt} \sin 2mt + \frac{dP}{dt} \cos 2mt \right) - \frac{a^3}{16} Q',$$

en faisant, pour abréger,

Q = 10y cos 6 sin 
$$(a + p)$$
 mt + ay sin 6 cos  $(a + p)$  mt,  
Q' = 2y sin 6 sin  $(a + p)$  mt + 7ay cos 6 cos  $(a + p)$  mt.

Elles sont exactes en négligeant les puissances de « à partir de la cinquième inclusivement, soit en dehors des sinus et cosinus, soit dans les coefficiens du temps sous les sinus ou cosinus.

6. Si le moment d'inertie C relatif à l'axe de figure du mobile est moindre que A qui répond à un diamètre de son équateur, la quantité a sera négative, et a imaginaire; sin (a + p) mt et cos (a + p) mt se changeront en exponentielles; les valeurs précédentes de s et s' croîtront donc indéfiniment; et, quelque petit que soit l'augle  $\gamma$ , ces valeurs et celles de se cesseront d'être très petites, comme le suppose notre analyse, au bout

d'un tems plus ou moins considérable. On ne pourra donc faire usage des formules (12) que pendant un certain tems; et, pour déterminer la position du corps à une époque quelconque, il faudra reprendre les équations (1) et (2), et les traiter d'une autre manière.

Si, au contraire, on a C > A, les valeurs de s et s' données par les formules (12), et par suite la valeur de  $\theta$ , demeureront constamment très petites, comme la constante  $\gamma$ ; l'équateur s'écartera toujours très peu du plan de l'écliptique; et les formules (12) feront connaître, à un instant quelconque, son inclinaison et le lieu de son intersection sur ce plan, avec d'autant plus d'exactitude, toutes choses d'ailleurs égales, que l'on attribuera une plus petite valeur à l'inclinaison initiale  $\gamma$ .

Ainsi la stabilité du mouvement d'un solide de révolution, autour d'un diamètre mobile de son équateur, et produit par la seule action d'un corps attirant qui tourne autour du centre de ce solide, exige que le moment d'inertie relatif à son axe de figure surpasse celui qui répond au diamètre équatorial; ce qui aura lieu, en effet, si le solide est aplati à ses pôles, en le supposant homogène ou composé de couches concentriques dont les densités varient de son centre à sa surface.

Cette condition étant remplie, et l'aplatissement étant supposé assez petit pour que « soit une petite fraction dont on puisse négliger, comme nous l'avons fait, la cinquième puissance; les déplacemens de l'équateur, conclus des équations (12) en y mettant  $\theta$  sin  $\psi$  et  $\theta$  cos  $\psi$  au lieu de s et s' (n° 3), seront soumis à deux sortes d'inégalités périodiques: les unes dépendantes des sinus et cosinus de l'angle 2mt, dont la période sera, conséquemment, d'une demi-année, c'est-à-dire, égale à la durée d'une demi-révolution du corps attirant; les autres rélatives aux sinus et cosinus de l'angle (a + p)mt, dont la période sera à l'année entière comme l'unité est à la fraction a + p, ou  $a(1 + \frac{1}{8}a^a)$ . Les premières inégalités seront donc les plus rapides; et parce que les coefficiens de lsin (a + p)mt et cos (a + p)mt ont  $\frac{1}{4}a^a$  pour facteur dans les formules (12), on voit que les amplitudes de ces inégalités à courtes périodes seront aussi beaucoup moindres que celles des autres inégalités.

Si l'on veut seulement connaître, pendant toute la durée du mouvement, l'inclinaison moyenne de l'équateur sur le plan de l'éoliptique, et le lieu moyen de son intersection avec ce plan, on supprimera, dans les expressions de θ et √ qui se déduiront des équations (12), les termes dépendans de l'augle 2mt; ce qui réduira ces expressions à une forme beaucoup plus simple, que nous déterminerens dans le numéro suivant. On devra restituer les termes supprimés lorsqu'en

voudra déterminer, à une époque quelconque, la position vraie du mobile, qui différera très peu de sa position moyenne, excepté dans un cas particulier dont nous nous occuperons dans la suite.

7. Désignons par k et k' les parties des formules (12) indépendantes de l'angle mt, et par  $\frac{1}{4} u^2 \pi$  et  $\frac{1}{4} u^2 \pi'$  les parties qui en dépendent, de sorte qu'on ait

$$s = k + \frac{1}{4}a^2\pi, \quad s' = k' + \frac{1}{4}a^2\pi'.$$

D'après ce qu'on a vu précédemment (n° 3), le rapport  $\frac{s}{s'}$  sera la tangente de la longitude de l'un des équinoxes. Si donc on prend pour le lieu moyen de cet équinoxe celui qui est déterminé par la formule

tang 
$$\psi = \frac{k}{k}$$
,

et si l'on représente par  $\psi + \delta$ , ce que devient l'angle  $\psi$  relativement à l'équinoxe vrai, de manière que nous ayons, en même tems,

tang 
$$(\psi + \delta) = \frac{k + \frac{1}{4} a^2 \pi}{k' + \frac{1}{4} a^2 \pi'}$$
;

en vertu de la formule

tang 
$$\delta = \frac{\tan (1 + \delta) - \tan \psi}{1 + \tan \psi \tan (1 + \delta)}$$

relative à la tangente de la différence de deux angles, nous aurons

tang 
$$\delta = \frac{\alpha^2 (k' \pi - k \pi')}{4(k^2 + k'^2) + \alpha^2 (k \pi + k' \pi')}$$
;

ce qui montre que l'angle d' demeurera très petit pendant toute la durée du mouvement, en excluant le cas où les quantités k et k' sont toutes deux très petites, qui est celui que nous examinerons plus loin en particulier.

L'équinoxe vrai s'écartant ainsi très peu de l'équinoxe moyen, à toutes les époques, le mouvement de l'un de ces deux points sera révolutif ou oscillatoire, en même tems que celui de l'autre. La même remarque convient à l'axe instantané de rotation: sa position vraie s'écartera constamment très peu de son lieu moyen, et, pour déterminer la nature, révo-

Autive ou oscillatoire, de son mouvement sur l'équateur, il suffire de considérer le mouvement de l'axe moyen.

Cela posé, substituons dans les seconds membres des équations (12) les valeurs de P, P', Q, Q', p; supprimons les termes dépendans de l'angle aussi, et saisons, pour abréger,

$$g = 1 - \frac{a^{2}}{4}, \quad h = 1 + \frac{7a^{2}}{8},$$

$$g' = 1 + \frac{a^{2}}{4}, \quad h' = 1 - \frac{a^{2}}{8},$$

$$g = 1 + \frac{a^{2}}{8}.$$

Nous auross . .

$$\theta \sin \frac{1}{2} = gy \sin \frac{\pi}{2} \cos \frac{\pi}{2} ahy \cos \frac{\pi}{2} \sin \frac{\pi}{2} amt, 
\theta \cos \frac{1}{2} = g'y \cos \frac{\pi}{2} \cos \frac{\pi}{2} ah'y \sin \frac{\pi}{2} \sin \frac{\pi}{2} amt,$$
(13)

pour déterminer à très peu près l'inclinaison moyenne de l'équateur sur le plan de l'écliptique et le mouvement moyen des équinoxes; en vertu des équations (q), aous aurons de même

$$a \sin \zeta = -aqgmy \sin \zeta \sin aqmt - \frac{1}{2} a^2qhmy \cos \zeta \cos aqmt,$$

$$a \cos \zeta = aqg'my \cos \zeta \sin aqmt + \frac{1}{2} a^2qh'my \sin \zeta \cos aqmt,$$
(14)

pour les équations d'où dépendent la vitesse angulaire moyenne et le mouvement moyen de l'axe instantané de rotation; et il s'agira maintenant de développer les conséquences de ces équations (13) et (14).

8. L'inclinaison moyenne de l'équateur sur l'écliptique ne peut être nulle à moins que les seconds membres des deux équations (13) ne soient sero ; ce qui exige que l'on ait

g sin 
$$C$$
 cos  $aqmt = \frac{1}{2} ah \cos C \sin aqmt$ ,  
 $\frac{1}{2} ah' \sin C \sin aqmt = g' \cos C \cos aqmt$ ;

d'où l'on conclut

$$agh' \sin^2 C = ag'h \cos^2 C.$$
 (15)

Or, si l'on substitue dans cette équation de condition, à la place de g', le la l'on méglige la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la la quatrième paissainé de la la quatrième paissainé de la la quatrième paissainé de la la quatrième paissainé de la la quatrième paissainé de la la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissainé de la quatrième paissaine de la quatrième paissaine de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la quatrième de la qu

et, par consequent,

$$\pm 6 = 45^{\circ} + \frac{3}{3} a^{3}$$
, on  $\pm 6 = 180^{\circ} - (45^{\circ} + \frac{3}{3} a^{3})$ .

Il s'ensuit donc que si la distance initiale du Soleil à l'équinoxe le plus voisin a été différente d'un demi-angle droit, on, plus exactement, de  $45^{\circ} + \frac{3}{5} e^{\circ}$ , l'équateur n'attoindra jameis le plan de l'écliptique, g'est-à-dire, que dans son mouvement moyen il restera et escillera toujours d'un même côté de ce plan. Nous examinerons plus loin le cas particulier où l'angle  $\pm \mathcal{L}$  a l'une des deux valeurs précédentes, qui rentre dans celui où les quantités k et k' peuvent être toutes deux très petites, et dont nous ne nous occupons pas actuellement.

En vertu des équations (13), on a

$$\theta^{2} = \gamma^{a} \left[ (g^{a} \sin^{a} \theta + g'^{a} \cos^{a} \theta) \cos^{a} aqmt \right]$$

$$- \alpha(gh + g'h') \sin \theta \cos \theta \sin \alpha qmt \cos \alpha qmt$$

$$+ \frac{1}{4} \alpha^{a} (h^{a} \cos^{a} \theta + h'^{a} \sin^{a} \theta) \sin^{a} \alpha qmt \right];$$

on déterminera donc les plus grands et les plus petits écarts de l'équateur, à partir du plan de l'écliptique, en égalant à zéro la différentielle par rapport à s de cette valeur de F; ce qui donne

$$a (gh + g'h') \sin 6 \cos 6 (\sin^2 aqmt - \cos^2 aqmt) - 2 [(g^2 - \frac{1}{4}a^2h'^2) \sin^2 6 + (g'^2 - \frac{1}{4}a^4h^2) \cos^2 6] \sin aqmt \cos aqmt = 0.$$

On tirera de cette équation deux valeurs de tang aque, dont l'une répondra aux minima de l'inclinaison  $\theta$ , et l'autre à ses maxima; et comme une tangente donnée appartient à une série d'angles croissant par des différences égales à 180°, il s'ensuit que l'intervalle entre deux maxima on deux minima consécutifs sera constant et égal à  $\frac{180°}{aqm}$ . Connaissant aînsi les époques des plus grandes et des moindres valeurs de  $\theta$ , l'expression de  $\theta$  fera aussi connaître leurs valeurs. Pour plus de simplicité, si l'on néglige « dans les coefficiens de l'équation précédente, elle se réduira à

a  $\sin 2\theta (\sin^{\alpha} aqmt - \cos^{\alpha} aqmt) - 2 \sin aqmt \cos aqmt = 0;$ d'où l'on tire, à très peu près,

tang 
$$aqmt = \frac{2}{a\sin 26}$$
, tang  $aqmt = -\frac{1}{1}a\sin 26$ ;

au moyen de quoi l'on aura, aussi à très peu près,

$$l=\frac{1}{2}m\gamma\cos2\theta$$
,  $l=\gamma$ ,

pour les plus petites et les plus grandes inclinaisons moyennes de l'équateur.

D'après les formules (14), il faut aussi que l'équation (15) ait lieu pour que la valeur moyenne de « puisse être égale à zéro; ce qui n'empeche pas que la vitesse angulaire vesie ne soit nulle à l'origine du mouvement et à d'autres époques, en vertu des inégalités à courte période dont elle est affectée. Si l'équation (15) n'a pas lieu, les maxima et les minima de la vitesse moyenne répondront aux minima et aux maxima de l'inclinaison, et ils auront pour valeurs

$$a = aqm\gamma$$
,  $a = \frac{1}{2}a^2qm\gamma \cos 26$ .

9. Les équations (13) donnent aussi

tang 
$$\psi = \frac{g \sin 6 \cos aqmt - \frac{1}{2} ah \cos 6 \sin aqmt}{g' \cos 6 \cos aqmt - \frac{1}{2} ah' \sin 6 \sin aqmt}$$
 (16)

En différentiant cette formule, on en déduit

$$\frac{d\downarrow}{dt} = \frac{a^2 m \eta \gamma^4}{2t^2}, \quad (17)$$

où l'on a fait, pour abréger,

$$\eta = gh'\sin^2 C - g'h\cos^2 C$$
,

et mis 6 à la place de sa valeur précédente.

Par hypothèse, l'équation (15) n'ayant pas lieu, la quantité n n'est pas nulle, et la différentielle de l'angle  $\psi$  ne le sera pas non plus. La formule (17) montre, de plus, que la valeur de  $\frac{d\psi}{dt}$  aura constamment le même signe; par conséquent, l'angle  $\psi$  eroîtra tonjours dans le même sens, et le mouvement des équinoxes sera révolutif. En ayant égard aux valeurs de g, g', h, h', celle de n peut être écrite ainsi:

$$\eta = (\tan g^{2} - 1 - \frac{3}{2} a^{2}) (1 - \frac{3}{8} a^{2}) \cos^{2} c;$$

d'où l'on conclut que cette constante n, et par suite la valeur de  $\frac{d\psi}{dt}$ , seront positives ou négatives, selon que l'angle 26 sera plus grand ou moindre que  $90^{\circ} + \frac{3}{4}$  seront positives ou négatives, selon que l'angle 26 sera plus grand ou moindre que  $90^{\circ} + \frac{3}{4}$  seront nature du signe : s'il est plus grand, l'angle  $\psi$  augmentera continuellement; et comme il est compté en sens contraire du mouvement du Soleil (n° 1), le mouvement des équinoxes sera rétrograde : le contraire aura lieu si l'on a  $26 < 90^{\circ} + \frac{3}{4}$  seront pour s'et ou rétrograde ; le contraire aura lieu si l'on a  $26 < 90^{\circ} + \frac{3}{4}$  seront pour s'et ou rétrograde ; selon qu'à l'origine du mou-

ŧ

vement, c'est-à-dire, à l'époque où la vitesse de rotation a été upposée nulle, la distance angulaire du Soleil à l'équinoxe le plus voisin était plus petite ou plus grande qu'un demi-angle droit, ou, plus exactement, plus petite ou plus grande que 45° + \frac{3}{5} a^2.

La formule (17) montre aussi que la vitesse angulaire  $\frac{d\psi}{dt}$  du mouvement des équinoxes varie en raison inverse du carré de l'inclinaison
de l'équateur sur le plan de l'écliptique; en sorte que ses maxima et
ses minima répondront aux minima et aux maxima de l. Abstraction
faite du signe, sa plus grande et sa plus petite valeur, pendant la durée de
chaque révolution, seront, à très peu près,  $\frac{2m}{\cos 26}$  et  $\frac{1}{2}$  d'un cos 26.

Quant à cette durée, on la déterminera en observant que, d'après la formule (16), tang y reprend une première fois le même signe et la même grandeur, lorsque l'angle agmi augmente de 180°; ce qui suppose que l'angle 🗸 augmente en même temps de 180°, et que les deux équinoxes prenuent la place l'un de l'autre : l'angle aqmi augmentant encore de 180°, l'angle 4 éprouve de nouveau cette même augmentation, et les équinoxes reviennent à leurs positions primitives. Il suit de la que la durée de chaque révolution entière de l'intersection de l'équateur et du plan de l'écliptique est égale à  $\frac{360^{\circ}}{agm}$ , c'est-àdire, qu'elle est à la longueur de l'année comme l'unité est à la fraction aq, très peu différente de «. Pendant chaque révolution, l'inclinaison 6 atteint deux fois son maximum et deux fois son minimum, de sorte que le tema d'une oscillation entière de l'équateur est moitié de celui d'une révolution équinoxiale. L'un et l'autre sont indépendans de la quantité y, supposée très petite, dont l'équateur a été primitivement écarté du plan de l'écliptique; et c'est ce qui arrive, en effet, pour tous les mouvemens périodiques des corps écartés un tant soit peu de leur position d'équilibre; laquelle position repond ici h y == 0.

Si l'on suppose, pour fixer les idées, que le mobile soit un ellipsoïde homogène; si l'on prend le demi-axe des pôles pour unité, et que l'on représente par 1 + 6 le rayon de son équateur, on aura, d'après les formules connues pour la détermination des momens d'inertie,

$$A = \frac{1}{6}M[1 + (1 + \epsilon)^4], \quad C = \frac{2}{5}M(1 + \epsilon)^4;$$

Métant la masse de l'ellipsoïde. En négligeant le carré de son aplatisse-

ment , on aura donc

$$\mathbf{a}^{2} = \frac{3(\mathbf{G} - \mathbf{A})}{2\mathbf{A}} = \frac{3\mathbf{e}}{2};$$

d'où il résulte que si cest, par exemple, un 300°, « sera à peu près un 15°, et chaque révolution des équinoxes s'achevera en près de 15 années. En supposant que l'angle & soit zéro ou 90°, leur plus grande vitesse sugar-laire sera à peu près double de celle du Soleil, et sa moindre valeur en sera environ un 450°.

Relativement à l'axe instantané de rotation, les équations (14) conduisent à des conséquences semblables à celles qu'on vient d'énoncer en détail, et qui se rapportent à la ligne des équinoxes. Le mouvement de cet axe sera aussi révolutif; la durée de chaque révolution sera la mêma que pour la ligne équinoxiale; la vitesse angulaire de l'axe instantané variera en raison inverse du carré de la vitesse moyenne de rotation autour de cet axe; les époques de ses maxima et de ses manima répondront à celles des minima et des maxima de la vitesse des équinoxes.

10. Examinous actuellement le cas particulier où l'angle 6 différe très peu de ± 45°, et où l'on a

en désignant par f une fraction ou un nombre peu considérable; ce qui comprend la valeur de G qui satisfait à l'équation (15), et pour laquelle on aurait  $f = \frac{3}{8}$ . On prend pour l'équinoxe du printems, auquel répond l'angle G, celui qui était le plus rapproché du Soleil à l'origine du monvement; le signe supérieur ou le signe inférieur aura lieu selon qu'à cette époque le Soleil se trouvait, dans le sens de son mouvement, en avant su en arrière de cet équinoxe.

Relativement à la double valeur de  $\mathcal{E}$  que nous supposons, les parties des seconds membres des équations (12), indépendantes de l'angle 2mt, et que l'on a désignées par k et k' dans le n° 7, se réduiront, pour certaines valeurs de  $\ell$ , à des quantités très petites qui auront  $a^3$  pour facteur. Pour ces valeurs de  $\ell$ , on ne pourra plus négliger les parties périodiques  $\frac{1}{4}a^2 = et \frac{1}{4}a^2 = et$ 

En développant suivant les puissances de », nous aurons

$$\sin 6 = \pm \frac{1}{\sqrt{2}} \left( 1 + a^2 f - \frac{1}{2} a^4 f^4 - \text{etc.} \right),$$

$$\cos 6 = \frac{1}{\sqrt{2}} \left( 1 - a^4 f - \frac{1}{2} a^4 f^2 + \text{etc.} \right).$$

Je substitue ces valeurs dans celles de P et P', et celles-ci dans les équations (12); en y mettant aussi  $\theta$  sin  $\phi$  et  $\theta$  cos  $\phi$  au lieu de s et s', et négligeant toujours les puissances de supérieures à la troisième, on trouve

$$\theta \sin \downarrow = \pm \frac{\gamma}{\sqrt{2}} M \left( \cos aqmt \mp \frac{1}{2} aN \sin aqmt \right),$$

$$\theta \cos \downarrow = \frac{\gamma}{\sqrt{2}} M' \left( \cos aqmt \mp \frac{1}{2} aN' \sin aqmt \right),$$
(18)

où l'on a fait, pour abréger,

$$M = 1 + a^{2}f - \frac{a^{2}}{4} + \frac{a^{2}}{4}\cos 2mt \pm \frac{a^{2}}{4}\sin 2mt,$$

$$M' = 1 - a^{2}f + \frac{a^{2}}{4} - \frac{a^{2}}{4}\cos 2mt \pm \frac{a^{2}}{4}\sin 2mt,$$

$$N = 1 - 2a^{2}f + \frac{9a^{2}}{8} + \frac{a^{2}}{2}(\cos 2mt \pm \sin 2mt),$$

$$N' = 1 + 2a^{2}f - \frac{3a^{2}}{8} + \frac{a^{2}}{2}(\cos 2mt \pm \sin 2mt);$$

de sorte que M, M', N, N', sont des quantités périodiques, qui dépendent de l'angle 2mt, et dont les valeurs différent toujours très peu de l'unité. Dans ces quantités et dans les équations (18), les signes supérieurs répondent au signe supérieur de la valeur de C, et les signes inférieurs à son signe inférieur.

Si l'on donne à f la valeur  $f = \frac{1}{2}$  qui satisfait à l'équation (15), et que l'on supprime les termes périodiques dépendans des sinus et cosinus de l'angle 2011, la valeur de  $\psi$  déduite des formules (16) sera constante; ce qui s'accorde avec la formule (17) relative au lieu moyen de la ligne des équinoxes; mais, dans le cas dont nous nous occupons, la position moyenne du mobile à un instant quelconque peut différer beaucoup de sa position

vraie que nous allens déterminer d'après les équations (18), sans y rien supprimer.

11. On tire de ces équations

$$\frac{\tan q + \tan q}{\tan q (\pm 45^{\circ})} = \frac{M (\cos aqmt \mp \frac{1}{6}aN \sin aqmt)}{M'(\cos aqmt \mp \frac{1}{6}aN' \sin aqmt)}.$$
 (19)

Or, tant que cos aqmi ne sera pas très petit, il est évident que cette formule différera très peu de l'unité, et que l'angle  $\checkmark$  différera aussi très peu de  $\pm$  45°; par conséquent, la ligne des équinoxes s'écartera d'abord très peu de la position correspondante à  $\checkmark = \pm$  45°; et elle fera de très petites oscillations de part et d'autre d'une droite à peu près immobile.

Ce mouvement vibratoire durera jusqu'à ce que l'angle aquet soit devenu très peu différent de 90°; et il cessera aussi d'avoir lieu à toutea les époques où aquet différera très peu d'un multiple impair de l'angle droit. Cela étant, désignons par i un nombre entier quelconque, par s le rapport de la circonférence au diamètre, et par u une variable positive ou négative, à laquelle on n'attribuera jamais de valeurs considérables; et supposous qu'on ait

$$aqml = \frac{1}{2}(2i - 1)\pi = \frac{1}{2}a - a\mu;$$

il en résultera

$$\cos aqmt = -(-1)^{l} \left[ \pm \frac{1}{2} a + au + \frac{a^{3}}{1 \cdot 2 \cdot 3} \left( \mp \frac{1}{2} - u \right)^{3} + \text{etc.} \right],$$

$$\sin aqmt = -(-1)^{l} \left[ 1 - \frac{a^{4}}{4 \cdot 2} \left( \mp \frac{1}{2} - u \right)^{4} + \text{etc.} \right].$$

En négligeant toujours le quatrième paissance de «, et suppriment ensuite le facteur — (— 1)'s qui sera commun au numérateur et au dénominateur de la formule (19), nous aurons

$$\frac{\tan \varphi \downarrow}{\tan \varphi (\pm 45^{\circ})} = \frac{M \left[u - u^{\circ} \varphi (i, u)\right]}{M' \left[u - u^{\circ} \varphi'(i, u)\right]}, \quad (20)$$

où l'an a conservé M et M' à la place de leurs expressions, et fait, pour abréger,

$$\begin{split} \phi(i,u) &= \frac{1}{6} \left( \pm \frac{1}{2} + u \right)^3 \mp \frac{1}{4} \left( \pm \frac{1}{2} + u \right)^4 \\ &= f \pm \frac{9}{16} \pm \frac{1}{4} \cos \left[ \frac{(2i-1)\pi}{\alpha q} \pm \frac{1}{q} - \frac{2u}{q} \right] - \frac{1}{4} \sin \left[ \frac{(2i-1)\pi}{\alpha q} \pm \frac{1}{q} - \frac{2u}{q} \right], \\ \phi'(i,u) &= \frac{1}{6} \left( \pm \frac{1}{2} + u \right)^3 \mp \frac{1}{4} \left( \pm \frac{1}{2} + u \right)^4 \\ &\pm f \mp \frac{3}{16} \pm \frac{1}{4} \cos \left[ \frac{(2i-1)\pi}{\alpha q} \pm \frac{1}{q} - \frac{2u}{q} \right] + \frac{1}{4} \sin \left[ \frac{(2i-1)\pi}{\alpha q} \pm \frac{1}{q} - \frac{2u}{q} \right]. \end{split}$$

Il s'agira donc de discuter cette formule (20), et d'énoncer les conséquences singulières qui s'en déduisent. Pour fixer les idées, nous prendrons les signes supérieurs dans cette équation.

On fera d'abord i = 1; et tant que la variable u ne sera pas devenue très petite, l'angle 4 différera toujours très peu de 45°. Mais le tems t croissant continuellement, la variable u décroîtra de même; il arrivera donc un instant où l'on aura  $u = \kappa^2 \varphi(x, u)$ , et un autre instant où l'on aura  $u = a^{\circ} \phi'(i, u)$ . Les valeurs de u qui répondront à ces deux époques seront, à très peu près,  $u = \alpha^{\circ} \phi(1, 0)$  et  $u = \alpha^{\circ} \phi'(1, 0)$ ; pour ces valeurs particulières, on aura tang ↓ = o et tang ↓ = ± ∞; et quand la variable u, en devenant négative, aura cessé d'être très petite, ou sera seulement devenue très grande par rapport à la fraction «, on aura de nouveau tang  $4 = \tan 45^{\circ}$ , à très peu près. Or, si l'on a  $\phi'(1,0) - \phi(1,0) > 0$ , la valeur  $u = \phi'(1, 0)$  arrivera la première. Pour cette valeur, on aura tang ↓ = ∞ et ↓ = 90°; au-delà tang ↓ sera négative, et l'angle  $\downarrow$  obtus. Pour  $u = \phi(1, 0)$ , on aura tang  $\downarrow = 0$  et  $\downarrow = 180^{\circ}$ ; et, ensuite, tang 4 = tang 45° répondra à 180° + 45°. Si, au contraire, on suppose  $\varphi(1,0) - \varphi'(1,0) > 0$ , ce sera la valeur  $u = \varphi(1,0)$ qui aura lieu la première; pour cette valeur, on aura tang ↓= o et  $\downarrow = 0$ , et pour  $u = \phi'(1, 0)$ , on aura ensuite tang  $\downarrow = -\infty$  et  $\psi = -90^\circ$ ; enfin, tang  $\psi = \tan 45^\circ$  répondra à  $\psi = -180^\circ + 45^\circ$ . Par conséquent, dans les deux cas, la ligne des équinoxes parcourra, en un tems très court, un angle de 180°; en sorte que les deux équinoxes se trouveront avoir pris la place l'un de l'autre; mais, dans le second cas, ce mouvement aura lieu dans le sens de celui du Solei!, et, dans le premier cas, en sens contraire.

Parvenue à sa nouvelle position, cette ligne fera, une seconde fois, de petites oscillations qui dureront jusqu'à ce que  $\alpha qmt$  ait augmenté d'une quantité peu différente de  $\pi$ ; alors, en faisant i=2 dans la formule (20), on en déduira des conséquences semblables à celles qu'on vient d'énoncer; et ainsi de suite.

Dans le cas particulier dont nous nous occupons, le mouvement de chaque équinoxe consistera donc en de petites oscillations qui auront lieu alternativement de part et d'autre des extrémités d'une même droite. Chaque série d'oscillations durera pendant un tems égal à

 $\frac{\pi}{aqm}$ , excepté la première, dont la durée sera réduite à moitié. Deux

séries successives seront séparées par un très petit intervalle de tems. Dans les renversemens successifs de la ligne des équinoxes, les déplacemens de cette droite seront rétrogrades ou directs par rapport au mouvement du Soleil, selon que les différences  $\phi'(1, 0) - \phi(1, 0)$ ,  $\phi'(2, 0) - \phi(2, 0)$ ,  $\phi'(3, 0) - \phi(3, 0)$ , etc., auront des valeurs positives ou négatives; et comme on a généralement

$$\phi'(i, o) - \phi(i, o) = 2f - \frac{3}{4} + \frac{1}{2} \sin \left[ \frac{(2i-1)\pi}{aq} - \frac{1}{q} \right],$$

de sorte que ces différences peuvent changer de signe par le changement du nombre entier i, il sera possible que les déplacemens de la ligne des équinoxes n'aient pas toujours lieu dans le même sens, pendant toute la durée du mouvement que nous considérons.

Nous avons pris les signes supérieurs dans la formule (20), ce qui revient à supposer qu'à l'origine du mouvement le Soleil se trouvait, dans le sens où il se meut, en avant de l'équinoxe le plus voisin; si le contraire avait lieu, on déduirait de cette formule des conséquences semblables, avec cette seule différence que les déplacemens successifs des équinoxes seraient rétrogrades ou directs, selon que les différences précédentes auraient des valeurs positives ou négatives.

Puisque le numérateur et le dénominateur de la Cormule (20) ne sont pas nuls à la même époque, il s'ensuit que les seconds membres des équations (18) ne sont pas zéro en même tems; par conséquent, l'inclinaison  $\theta$  n'est jamais tout à-fait nulle, et l'équateur oscille toujours d'un même côté de l'écliptique; mais les plus petits écarts de  $\theta$  qui ont lieu vers les époques où l'une des quantités  $u - \phi(i, u)$  et  $u - \phi'(i, u)$  est zéro, se trouvent avoir  $a^3$  pour facteur, et sont, en conséquence, beaucoup moindres que les minima de  $\theta$  relatifs au cas général (n° 8).

Les lois singulières du mouvement de la ligne des équinoxes sur l'écliptique, qui ont lieu dans le cas de  $c = \pm (45^{\circ} + s^{\circ}f)$ , et qu'on vient de décrire, conviennent pareillement au mouvement de l'axe instantané de rotation sur l'équateur.

12. Dans l'Exposition du Système du Monde, Laplace, après avoir

expliqué la cause de la précession des équinoxes (*), essaie d'en assigner les lois, autant qu'il est possible de le faire par le simple raisonnement et sans le secours de l'analyse.

Pour cela, il imagine que la masse du Soleil soit distribuée uniformément sur toute la circonférence de son orbite; puis il prend l'action exercée par cet anneau matériel sur le sphéroïde terrestre, pour l'action movenne du Soleil. Si la rotation de la Terre était nulle, il est évident que cette action moyenne ferait osciller l'équateur de part et d'autre du plan de l'écliptique, autour de la ligne des équinoxes qui resterait immobile. Or, Laplace conclut, d'un raisonnement assez difficile à saisir, que la rotation de la Terre fait passer dans la ligne des équinoxes le mouvement qui serait, sans cette rotation, dans l'inclinaison de l'équateur, et donne, réciproquement, à cette inclinaison la permanence qui aurait lieu dans la ligne des équinoxes. Il en conclut aussi que ce mouvement des équinoxes sera uniforme et toujours rétrograde, c'est-à-dire, en sens contraire du mouvement de rotation; et, en effet, l'analyse fait voir que le mouvement progressif des équinoxes est rétrograde ou direct, par rapport au mouvement apparent du Soleil, selon que le mouvement diurne de la Terre a lieu dans le sens de ce mouvement ou en sens contraire; d'où il résulte que le mouvement progressif des équinoxes a toujours lieu en sens contraire de la rotation de la Terre.

La substitution de l'action moyenne du Soleil, représentée par celle de l'anneau matériel, à l'action révolutive et complète de cet astre, revient évidemment à supprimer les termes périodiques dans l'expression de cette force variable; mais cette suppression n'est pas toujours permise, et il y a des cas dans lesquels elle peut induire en erreur sur la nature véritable du mouvement de la Terre autour de son centre de gravité. L'un de ces cas a lieu, par exemple, lorsque l'on suppose la vitesse n du mouvement diurne égale à zéro.

En effet, on en conclurait alors, comme on vient de le dire, que l'intersection de l'équateur et de l'écliptique, doit demeurer immobile, et qu'au contraire l'équateur doit atteindre l'écliptique et osciller de part et d'autre de ce plan; ce qui est contraire aux résultats relatifs à ce cas particulier, que nous avons déduits de l'analyse. Mais il est important d'observer que lors même que l'on supprime les termes périodiques des valeurs de s et s', ou de celles des angles s et \(\psi\), pour ne considérer que les positions moyennes de l'équateur, on ne doit faire

^(*) Livre IV, chapitre XIV.

cette suppression que dans les valeurs complètes de ces quantités, et après avoir déterminé les constantes arbitraires que contiennent les expressions de s et s'.

Ainsi, en suppriment dens ces expressions les termes dépendans des sinus et cosinus de 2mt, avant la détermination des constantes arbitraires D, E, D', E', on aurait (10° 4)

$$s = D \sin amt + E \cos amt,$$
  
 $s' = D' \sin amt + E' \cos amt;$ 

et comme on a (nº 3)

$$s = \gamma \sin \theta$$
,  $s' = \gamma \sin \theta$ ,  $\frac{ds}{dt} = 0$ ,  $\frac{ds'}{dt} = 0$ ,

pour t = 0, il en résulterait

$$D = 0$$
,  $D' = 0$ ,  $E = \gamma \sin \zeta$ ,  $E' = \gamma \cos \zeta$ ;

en sorte que l'on aurait, à un instant quelconque,

$$s = \theta \sin \psi = \gamma \sin \theta \cos \omega m t$$
,  
 $s' = \theta \cos \psi = \gamma \sin \theta \cos \omega m t$ ,

et, per conséquent,

$$\psi = 6$$
,  $\theta = \gamma \cos amt$ ;

ce qui répondrait à l'immobilité de la ligne des équinoxes, du moins dans son état moyen, et à des oscillations égales et isochrones de l'équateur de part et d'autre du plan de l'écliptique. Mais, au contraire, si l'en détermine d'abord les constantes D, E, D', E', contenues dans les expressions complètes de s et s', ce qui conduit aux formules (10) du n° 4, et si l'on supprime ensuite les termes dépendans de sin 2mt et ces 2mt dans ces formules; en mettant aussi l'unité au lieu de 1 ± ¼s², on aura

$$\theta \sin \psi = \gamma \sin \theta \cos^2 \alpha mt - \frac{1}{2} \alpha \gamma \cos \theta \sin \alpha mt$$
,  
 $\theta \cos \psi = \gamma \cos \theta \cos \alpha mt - \frac{1}{2} \alpha \gamma \sin \theta \sin \alpha mt$ ,

pour déterminer, dans une première approximation, la position moyenne de l'équateur à un instant quelconque; et ces formules donneront lieu à des conséquences confraires à celles qui se déduisent des valeurs précédentes  $\mathcal C$  et  $\gamma$  cos amt de  $\psi$  et  $\theta$ . Nous ne reviendrons pas de nouveau sur cos résultats, qui ont été suffisamment développés dans ce mémoire, et étendus à une seconde approximation.

P. S. Dans un second méruoire postérieur à celui qu'on vient de lire, et qui paraîtra incessamment dans le tome XIV des Mérmoires de l'Académie des Sciences, j'ai reconnu que l'on peut intégrer sous forme finie les équations (5) du n° 2; et de leurs intégrales exactes f'ai déduit toutes les conséquences exposées ci-dessus, auxquelles on est parvenu moins simplement par la méthode laborieuse des approximations successives.

#### NOTE

Sur la comparaison de la demi-toise de Vienne avec le mêtre français;

PAR M. DE PRONY.

Le gouvernement autrichien a adressé, en 1830, au Gouvernement français, un étalon de mesure, en acier non trempé, de la demi-toise de Vienne, et a témoigné le désir qu'on en fit la comparaison avec l'étalon de mètre en platine déposé à l'Observatoire royal de Paris.

L'Académie des Sciences (Institut royal de France), charges une commission, composée de feu M. Legendre et moi, de s'occuper de cette comparaison. Une pareille opération exigeait l'emplot d'appareils que l'Institut ne possédait pas, et ceux de l'Observatoire, dont on se servait alors pour diverses observations, n'étaient pas encore disponibles, lorsque la mort de mon célèbre confrère désorganisa la commission dont nous étions membres.

Dans cet état de choses, M. le baron Huguel, premier conseiller de l'ambassade d'Autriche, me consulta sur les moyens d'obtenir un travail dont on attendait les résultats, à Vienne, avec impatience, et je ne pus pas lui indiquer d'expédient plus prompt pour son exécution que celui de m'en charger personnellement, bien entenda que mes déterminations pourront, lorsque les circonstances le permettront, être soumises à des vérifications ultérieures.

Je me trouve heureusement possesseur d'un mêtre en platine, dont j'ai fait l'acquisition lorsque j'étais membre de la commission chargés de

L'organisation du système métrique français; ce mètre, que mon confrère M. Mathieu et moi avons trouvé, d'après les vérifications les plus rigoureuses, parfaitement conforme à celui de l'Observatoire, est l'étalon auquel j'ai comparé la demi-toise de Vienne. Voici le détail des procédés par lesquels j'ai effectué cette comparaison.

Une des principales pièces de mes appareils était une forte règle de ser de 2 mètres et demi de longueur, parsaitement dressée par Le Noir, et saisant partie de son comparateur, dont j'ai donné la description dans le tome III de la Base du Système métrique décimal, ou Mesure de l'arc du méridien, etc., page 447 et suivantes. Un heurtoir fixe était solidement établi à une des extrémités de cette règle, le long de laquelle glissait, sans aucun jeu latéral, une boîte de cuivre qui en embrassait le dessus et les deux côtés; ce curseur était lui-même muni d'un heurtoir solidement assemblé à l'une de ses extrémités

Vers le bout de la grande règle opposé à celui qui portait le heurtoir fixe, et au milieu de sa largeur, se trouvait implanté un axe vertical conique autour duquel tournait une pièce de cuivre munie des articulations convenables, et à laquelle était fixée l'une des extrémités d'une verge d'environ 12 décimètres de longueur, portant à son autre extrémité un tracelet très fin et bien acéré.

Enfin, une règle de cuivre, bien dressée et polie, d'environ 15 centimètres de longueur, était vissée aur la boîte portant le henrtoir mobile, et placée de manière qu'une ligne très fine, tracée aur cette règle dans le sens de sa longueur, se trouvât exactement parallèle à l'axo de la grande règle, dans un plan vertical passant par cet axe (la face de la règle étant supposée horizontale).

Cos dispositions m'ont fourni un premier moyen de mesurer, bien exactement, l'excès du mètre en platine sur la demi-toise de Vienne, Le mètre étant posé sur la grande règle et en contact, par un de ses houts, avec le heurtoir fixe, la boîte portant le heurtoir mobile a été poussée de manière que ce heurtoir mobile fût en contact avec l'autre hout de la règle; dans cet état, j'ai fait, avec le tracelet ci-dossus montionné, un trait extrêmement sin coupant à angle droit la ligne tracée sur la règle vissée à la boîte portant le heurtoir mobile.

Le mètre en platine a été enlevé et remplacé par la demi-toise de Vienne (j'avais ôté deux pièces de cuivre formant saillie sar la surface de cette demi-toise), et ses extrémités mises en contact avec les deux heurtoirs, comme l'avaient été celles du mètre; j'ai fait alors avec le tracelet un second trait sur la règle vissée à la boîte portant le heurtoir mobile, et il est manifeste, d'après l'invariabilité tant de la lon-

gitude de la verge portant le tracelet que de la position de son centre de rotation, que la distance entre les deux traits est rigoureusement égale à la différence entre le mètre et la demi-toise (*).

Gette opération a été répétée vingt fois, savoir, cinq fois sur chaque face d'une première règle, qui a été remplacée par une seconde, sur laquelle j'ai tracé dix autres couples de traits, dont cinq aussi sur chaque face. Chaque couple était séparé des autres au moyen de petites variations que je faisais subir à la distance entre le tracelet et le centre fixe autour duquel il était assujetti à se mouvoir, toutes les précautions étant prises pour maintenir la parfaite invariabilité de cette distance pendant le tracé d'une même couple.

Un thermomètre centigrade de Pixii, placé à côté de l'appareil, s'est maintenu constamment entre 14° et 15° centigrades, valeur moyenne 14°,5 centigrades.

Ayant ainsi ces vingt longueurs établies sur des surfaces métalliques, il s'agissait de déterminer leur valeur moyenne, et j'aï employé divers procédés pour obtenir cette valeur. L'un de ces procédés consistait dans l'emploi de ce que je pourrais nommer un compas microscopique composé de deux microscopes à fil fixés sur un même support, avec les dispositions nécessaires pour faire varier la distance entre leurs axes parallèles, au moyen de vis de micromètres de ½ millimètre de pas, indiquant immédiatement les 2000 de millimètre sur des cadrans dont les divisions avaient environ 1 millimètre d'amplitude. Ayant pris, avec ce compas, la distance entre deux traits d'une même couple, sur une des deux règles oi-desses mentionnées, je pouvais, par l'emploi combiné du compas microscopique, de la règle portant la couple et d'un troisième microscope, répéter dix fois cette distance sur une règle divisée en millimètres par Le Noir, que je regarde comme un des ouvrages de division de l'igne droite les plus parfaits de ce célèbre artiste.

Les deux cents comparaisons ainsi faites, m'ont donné, valeur moyenne, pour l'excès du mètre sur la demi-toise de Vienne, savoir,

^(*) Ces deux traits sont des arcs de cercle, mais la différence cherchés n'est pas meine-exactement représentée, 1°. parce qu'elle existe entre les points d'intersection de ces arcs et de la ligue tracée, sur le milieu de la largeur de la règle, dans le sens de sa longueur; 2°. parce que ces arcs de cercle, extrémement petits par rapport au rayon dont ils sont décrits, se confondant semiblement avec leurs cordes. On peut s'assurer, par un esteul aisé, que la flèche d'un arc de cercle d'un millimètre de longueur, décrit d'un rayon de 1²⁰, 2 ou 1200 millimètres, n'est que d'environ un dix-millième de millimètre, et le sil le plus fin, placé au foyer du plus fort microscope, ne pourrait pas séparer, à l'œil, cet arc de sa conde.

om,0519008 sur une des règles, et om,0519040 sur l'autre règle; la différence = om,0000032, et la valeur moyenne = om,0519024; d'eà l'on conclut pour la longueur de la demi-toise de Vienne, en parties du mètre étalon en platine, à la température commune de 14°,5 centigrades, om,9480976.

Ce résultat est sensiblement le même que celui auquel je suis parvenu après divers autres modes de comparaison. Je vais dire quelques mots de celui qui donne le plus de précision. J'ai établi un comparateur à une des extrémités duquel est placé un heurtoir fixe; vers l'autre extrémité sont deux règles de laiton parallèles, divisées par Le Noir, l'une en millimètres, l'autre en quart de lignes de pied de Roi. La distance entre leurs arètes intérieures est de 68 millimètres; une plaque de cuivre de forme rectangulaire, faisant fonction de curseur, de même épaisseur que les règles divisées, d'une largeur égale à la distance intérieure de ces règles et de 160 millimètres de longueur, porte un heurtoir à chacune de ses extrémités, et sur chacun de ses côtés longitudinaux sont tracés des verniers de 50° de millimètres et de 100° de lignes.

Ce curseur glissant entre les règles graduées, peut servir immédiatement, au moyen d'un de ses heurtoirs et de ses verniers, à déterminer la différence entre deux mesures métalliques mises en contact, par un de leurs bouts, avec le heurtoir fixe. Mais l'appareil dont it fait partie m'a fourni des ressources beaucoup plus étendues pour multiplier les vérifications; j'ai fixé à l'extrémité du comparateur, du côté des règles graduées, une vis d'acier de 12 centimètres de longueur, dont les pas de vis, de \(\frac{1}{2}\) millimètre, sont sous-divisés chacun en 100 parties par un cadran de \(\perifo}\) centimètres de diamètre. Cette vis, d'une précision remarquable, a été construite par feu Richer, artiste dont le mérite est bien connu; fixée sur la table du comparateur, le mouvement de son écrou faisait marcher un microscope à fil parallèlement aux règles graduées.

Le comparateur étant ainsi préparé, j'ai fixé sur le curseur une des règles sur lesquelles les couples de traits avaient été tracées, et à côté, sur le même curseur, une petite règle de 2 décimètres, divisée en demi-millimètres par Le Noir : dès lors j'ai pu, au moyen du compas microscopique, du troisième microscope ci-dessus mentionné et du quatrième microscope mu par la vis Richer, faire, pour chaque longueur donnée par une couple de traits, quatre observations simultanées, savoir, deux fournies par les règles fixes graduées et les verniers du curseur mobile, une troisième par la règle de demi-millimètres fixée sur ce curseur, et une quatrième par la marche de l'écrou de la vis Richer, parcourant

la longueur comprise entre deux divisions d'une même comple. Les procédés mécaniques de ces observations ne pourraient guère êtré bien comme cus sans figures.

En definitive, j'ai trouvé qu'à la température de 14°,6 centigrades, les demi-toise d'acier non trempé de Vienne valait, en parties du mêtre étamlon en platine, o^m,9480987; ce n'est que 10 au métre environ de plus que ce que j'avais trouvé par mes premières comparaisons. Les résultats obtenus à des températures différentes de 14°,5 y ent été ramenés par les règles de calcul données ci-après, dans les cas où cette réduction devenait nécessaire.

Ainsi, à la température de 14°,5 centigrades, la toise en acier de. Vienne vaut 1^m,8961974 mesurés sur l'étalon du mètre en platine. Ce rapport, bon à employer dans les calculs de grande Géodésie, pent, peur l'étalonnage, d'après le mètre français, des mesures à l'usage des arpenteurs, des architectes, etc., se réduire à 1^m,8962.

Une table de concordance des mesures étrangères et françaises, que j'ai publiée dans les Annuaires du Bureau des Longitudes de 1831 (page 142 et suivantes), et 1832 (page 147), porte, d'après M. Frédéric Lohman, le pied de Vienne à o^m,316103, ce qui donne pour la demi-toise o^m,948309, évaluation qui excède la mienne de o^m,0002103 = ½ de millimètre à très peu près.

Après quelques recherches infractueuses sur les causes de cette différence, j'ai trouvé, dans le Traité de Métrologie ancienne et moderne de M. Saigey, page 170, une comparaison de la toise de Vienne et de celle de Paris, donnée, en 1766, par l'astrenome Liesganig, d'après laquelle le rapport entre les deux toises serait celui de 100000 à 102764. M. Saigey ne donne aucun détail sur les procédés employés pour la comparaison des deux mesures, ne dit pas si la température a été notés, ce qui a pu paraître peu nécessaire, la matière des deux mesures apparées étant probablement de fer ou acier non trempé.

Réduisant les 100000 de toise française en mètre, d'après le coefficient 1,94903659, inscrit dans l'Annuaire du Bureau des Longitudes, on trouve que la valeur donnée par Liesganig de la toise de Vienne est de 1^m,896614, et celle de la demi-toise de 0^m,948307; d'où l'on déduit le pied de Vienne = 0^m,3161023, résultat qu'on peut regarder comme identique avec celui que j'ai donné dans l'Annuaire ei-desses cité, d'après M. Lohman, qui, selon toute apparence, l'a donné d'après Liesganig.

Je ne crois pas, vu l'attention avec laquelle j'ai fait mes observations et. les moyens de précision que j'ai employés, qu'on puisse dé-

Digitized by Google

daire de la demi toise de Vienne qui m'a été confiée une valeur, en mêtre, égale à celle qui se déduit de la valeur en toise française donnée par Liesganig; il me paraît plus vraisemblable que cet astronome, ou n'a pas employé des procédés aussi exacts que les miens, ou s'est servi d'une ancienne toise française qui n'était pas rigoureusement conferme à l'étalon authentique de la toise déposé à l'Observatoire royal de Paris, celui auquel se rapporte immédiatement l'expression du mêtre définitif en anciennes mesures.

Je vais examiner l'influence que les variations et combinaisons diverses de températures pourraient avoir sur les rapports de longueur des mesures que j'ai comparées; j'emploierai pour cet examen des règles de calcul analogues à celles que j'ai données dans un rapport fait à l'Institut royal de France, sur le pied anglais, rapport qu'on trouve dans le 3 volume ci-dessus mentionné, de la Base du Système métrique décimal, etc., à la suite de mon mémoire sur le Comparateur de Le Noir.

Je désigne par m la mesure à comparer, par m la mesure étalon, et par T la température commune à laquelle la comparaison des deux mesures a été faite.

Lorsque la température de m varie de la distance entière entre la congélation et l'ébullition de l'eau, la variation de sa longueur est égale à une fraction de cette même longueur que je représente par \( \frac{1}{a} \); dans les mêmes circonstances, la variation de longueur de m serajune fraction de cette longueur représentée par \( \frac{1}{a} \). On sait qu'à partir du terme de la congélation, et même d'un terme inférieur, ces variations de longueur se forment par des accroissemens successifs sensiblement proportionnels aux accroissemens correspondans de température, ce quija lieu jusqu'au terme de l'ébullition et même jusqu'à une température plus élevée.

Ainsi la température de m, supposée égale à T lors de sa comparaison avec  $\mu$ , devenant  $T \pm t$ , la longueur de m deviendra  $m \pm \frac{t}{a}$ ,  $m = \left(1 \pm \frac{t}{a}\right)m$ ; et si la température de  $\mu$  devient  $T \pm r$ , sa

longueur sera 
$$\mu \pm \frac{\tau}{a} \mu = \left(1 \pm \frac{\tau}{a}\right) \mu$$
.

Désignant par K le rapport des longueurs ainsi variées, en aura

$$K = \frac{1 \pm \frac{t}{a}}{1 \pm \frac{v}{a}} \cdot \frac{m}{\mu}.$$

Le rapport  $\frac{m}{\mu}$ , constant dans chaque cas particulier, peut être représenté par la lettre unique k, et l'on a la relation

$$K = \frac{a \pm t}{a + s} \cdot \frac{a}{a} k.$$

La quantité k est donnée par les expériences desquelles on a déduit le rapport  $\frac{m}{\mu}$ ; à la température T, a et a sont connus pour chaque espèce de métal. Ainsi,  $\frac{a}{a}k$  est une constante, et l'on peut poser, pour abréger,

$$\frac{d}{d}k = A.$$

La relation entre les variables K, t et  $\tau$  sera exprimée par l'équation fort simple

$$K = \frac{a \pm t}{a \pm \tau} \cdot A \cdot \dots (1)$$

1°. Une valeur de a gravée sur une des faces de la demi-toise de

On a, pour calculer la constante A,

Vienne et rapportée au thermomètre de Réaumur; en réduisant cette valeur au thermomètre centigrade, et prenant pour unité thermométrique l'espace entier compris entre la congélation et l'ébullition de l'eau, on trouve a=922,50, d'où  $\frac{1}{a}=0,001084$ . J'emploierai cette valeur, qui diffère peu de 0,0010791, qu'on trouve dans l'Annuaire pour l'acier non trempé, et diffère davantage du coefficient 0,0012205 porté, dans le même Annuaire, pour le fer doux forgé.

- 2°. Une valeur de « qu'on trouve, dans l'Annuaire, égale à 1167; d'où = 0,0008569.
  - 3°. La valeur de  $\frac{m}{\mu}$ , ou k, donnée ci-dessus et égale à 0,9480987. On déduit de ces données

Il ne faut pas oublier que les degrés de chaleur t et  $\tau$  se comptent à partir de la température commune T des deux corps, qui avait lieu lorsqu'on a déterminé le rapport  $\frac{m}{\mu}$  on k. Ainsi, pour des valeurs quelconques de t et  $\tau$ , les températures correspondantes effectives sont  $T \pm t$  et  $T \pm \tau$ .

On déduit de l'équation (1) la suivante, dont je ferai usage cî-après,

$$t = \frac{K}{A} (a \pm \tau) - a \dots (2)$$

Je vais appliques l'équation (1) à la détermination du rapport K qui existerait entre les deux mesures si l'étalon en platine passait à la température zero, ce qui suppose  $\tau = -0.145$ , la demi-toise de Vienne conservant la température T, ce qui suppose t = 0. On a pour calculer ce rapport l'équation

$$K = \frac{9^{22},50}{1167 - 0,145} \times 1,1993836 = 0,948217.$$

Ce résultat K = 0,948217 se rapproche de celui de Liesganig, sans cependant lui être favorable, vu la diversité des circonstances auxquelles tient sa détermination.

Je vais maintenant chercher ce que deviendrait le rapport K si les mesures à comparer étaient l'une et l'autre à la température de la glace.

On a, dans ce cas, t== = 0,145, et l'équation (1) devient

$$K = \frac{922,5-0,145}{1167-0,145} \times 1,1993836 = 6,9480679.$$

La différence entre ce résultat et celui qui a été obtenu à la température commune n'est que de 30 de millimètre.

Je terminerai ces applications en faisant usage de l'équation (2) pour trouver à quelle température il faudrait mettre la demi-toise de Vienne pour que son rapport avec le mêtre en platine, supposé à la température zéro, fût celui qu'on déduit des nombres de Liesganig.

Faisant, dans l'équation (2), K = 0.948307 et  $\tau = -0.145$ , on a

$$\epsilon = \frac{0.948307}{1.1993836} \times (1167 - 0.145) - 922.50 = 0.088.$$

Ajoutant cette valeur de t=0,088 à celle de T=0,145, on a 0,233,

qui, dans la notation ordinaire, représentent 23°,3 centigrades, ou 18°,6 Réaumur, pour la température à laquelle il faudrait porter la demi-toise de Vienne, le mètre en platine étant à la température zéro, si l'on voulait que les deux mesures eussent entre elles le rapport conclu des nombres de Liesganig.

Salta   Rep. de Buenos-Ayres	24.35	67.36
Tarija	21.36	67.03

Les déterminations précédentes m'ontétéenvoyées comme ayant étéfaites par la commission des Limites, nommée pour fixer la ligne de frontières entre les territoires espagnol et portugais, en vertu des stipulations du traité de San-Ildefonce. En les comparant aux miennes, on verra qu'elles offrent des différences notables pour la latitude de quelques points (Potosi),

^(°) La position de Potosi est déduite pour la latitude de banteurs méridiennes de « du Bélier, d'Aldébaran, de « d'Orion, de Canopus, etc. La longitude de 5 séries de bonnes distances de la Lune au Soleil observées le 25 décembre, le seul jour que j'aie pu en prendre.

⁽¹¹⁾ La position de la capitale de Bolivia résulte de 22 hauteurs méridiennes d'étoiles de chaque côté du zénith, observées pendant plusients jours, et de 21 séries composées de 80 observations de distances au Soleil, observées les 19, 20, 21 et 22 janvier 1827.

⁽¹²⁾ La latitude de Cochabamba résulte de hauteurs méridiennes de « de la Croix et de Canopus, observées le 7 mars, et la longitude de 5 séries de distances de la Lune à Régulus et à Aldébaran, prises le même jour.

mais surtout pour la longitude. Je ne sais par quel moyen ces longitudes ont été déterminées, quoique je présume qu'elles étaient conclues du transport du tems, ou même par de simples itinéraires depuis la cête de la mer du Sud, dont les points de départ étaient très mai déterminées en longitude à l'époque en question.

Il est évident pour moi que tous les points de l'intérieur du Haut-Pérou et de Bolivia ont été placés heaucoup trop à l'Ouest sur la carte d'Olme-dilla de la Cruz, carte qui a été copiée par tous les géographes jusqu'à ce jour. On peut en juger d'après la comparaison du tableau suivant, pour des points dont j'ai déterminé la position par de nombreuses séries de distances lunaires indépendantes de tout autre genre de détermination.

Lat et le	ong. de la ca	rte de la Cruz.	Lat. et long	. Pentland.	Différ.

A l'époque de la publication de la carte de la Cruz il n'existait augune observation astronomique, à ma connaissance, pour déterminer la position des endroits dans l'intérieur du Pérou. La commission des Limites avait bien les moyens d'y arriver quant à la latitude; aussi voit-on que les latitudes des points indiqués ci-dessus s'accordent, à quelques minutes près, avec celles que j'ai déterminées, tandis que les longitudes s'écartent énormément. Les observations de longitude de la commission des Limites, d'après ce que m'en a rapporté feu Don F. Bauza, qui possèdait les travaux manuscrits de l'expédition, se réduisent principalement à des éclipses des satellites de Jupiter et à quelques déterminations chronométriques. Quant aux premières, on sait aujourd'hui le peu de confiance qu'elles méritent, sans des observations correspondantes dans un observatoire fixe; et en ce qui touche les données fournies par les meilleurs chronomètres dans des voyages par terre, jé puis, d'après ma propre expérience, dire qu'elles ne méritent aucune espèce de confiance.

Des observations que j'ai faites dans l'intérieur du Pérou et dans la république de Bolivia, je crois pouvoir conclure que tous les points ont été jusqu'ici placés beaucoup trop à l'Ouest ou trop rapprochés des côtes de la mer du Sud. J'irai plus loin, en disant que les posi-

tions déterminées par la commission des Limites partagent les mêmes erreurs, et que par conséquent les géographes, jusqu'à ce jour, en portant trop à l'Ouest la position des différentes villes de Bolivia, ont beaucoup trop rétréci l'étendue de son territoire, en augmentant dans une égale proportion celle du territoire Brésilien.

### MÉMOIRE

Sur une méthode nouvelle pour la détermination des perturbations planétaires;

PAR M. G. DE PONTÉCOULANT.

Depuis quelques années M. Hansen, directeur de l'Observatoire de Seeberg, a publié sur la théorie des inégalités planétaires plusieurs mémoires curieux, soit par la nouveauté des idées, soit par l'importance des résultats numériques qu'ils renferment. Comme ces mémoires, épars dans divers recueils, sont écrits la plupart en latin, que le plus important de tous, celui qui traite des inégalités de Jupiter et de Saturne, ouvrage couronné par l'Académie de Berlin, a été composé dans la langue maternelle de l'auteur, ils n'ont peut-être pas eu en France toute la publicité qu'ils méritaient d'obtenir. Je me propose de réparer ici cette lacune dans l'histoire de la science, et comme l'étude spéciale que j'ai faite de cette partie de la théorie du système du monde, m'a conduit à suivre avec soiu tout ce qui se faisait sur le même sujet en Angleterre et en Allemagne, et en particulier les laborieuses recherches de M. Hansen, je crois être à même de donner une idée juste et claire des travaux de ce savant astronome. Mais dans cette analyse je ne m'astreindrai pas à suivre par ordre de dates les différens ouvrages de l'auteur, d'abord parce que cela m'entraînerait au-delà des limites qui me sont prescrites, et que d'ailleurs M. Hansen, revenant souvent, dans ses derniers mémoires, sur des sujets qu'il a déjà traités dans les précédens, il en résulterait des répétitions qu'on doit éviter, surtout dans les ouvrages scientifiques. Je m'attacherai donc spécialement à donner une idée précise des nouvelles méthodes imaginées par ce géomètre, à montrer en quoi elles différent de celles que ses prédécesseurs avaient adoptées; à en faire apprécier les avantages, à en signaler, s'il y a lieu, les inconvénieus. Pour parvenir à ce but, je suivrai toujours la marche qui me paraîtra y conduire le plus directement, en choisissant dans les divers mémoires de M. Hansen, parmi les démonstrations d'une même proposition, celle qui me semblera la plus propre à la mettre en évidence; et en substituant quelquefois aux déductions de l'auteur tout autre ordre de raisonnemens qui me paraîtront ou plus simples ou tendre plus directement vers le point auquel il veut parvenir : ce sera le meilleur moyen d'éviter les digressions qui font perdre de vue l'objet principal, et de donner quelque intérêt, je l'espère, à ce compte rendu des travaux du savant étranger.

Les mémoires de M. Hansen peuvent se diviser en deux parties distinctes. Dans la première il traite des inégalités planétaires, en ne portant l'approximation que jusqu'à la première puissance des masses perturbatrices, il applique ensuite à ses formules, pour les réduire en nombres, la méthode des quadratures mécaniques, et parvient à des résultats qui s'accordent, en général, d'une manière très satisfaisante avec les résultats obtenus par la méthode ordinaire d'approximation fondée sur la petitesse des excentricités et des inclinaisons des orbes planétaires. Dans la seconde partie, M. Hansen donne des formules qui s'étendent à toutes les puissances de la force perturbatrice, et en fait l'application à la détermination des deux grandes inégalités de Jupiter et de Saturne, en se bornant toutefois à considérer les termes de l'ordre du carré des masses. Nous ne nons occuperons ici que de la première partie de ces recherelies.; nons pousserous ensuite plus loin notre analyse si elle semble intéresser les géomètres, et il sera facile d'ailleurs de suivre les méthodes de l'auteur., lorsqu'il s'élère au curré et aux puissances supérieures des forces perturbatrices, si l'on a bien saisi ses formules relatives à la première approsimation.

Le but principal que s'est proposé M. Hansen dans son travail, est de déterminer, par les formules les plus simples et les plus faciles à adapter au calcul numérique, les trois variables que les astronomes emploient ordinairement pour déterminer la position des corps éélestes autour du Soleil. D'après cela, il semblerait que la méthode qui donne, par l'intégration directe des équations différentielles du mouvement troublé, les valeurs de ces coordonnées exprimées, au moyen de la fonction perturbatrice, devait être préférée à celle de la variation des constantes arbitraires; et, en effet, l'emploi de cette dernière méthode oblige à calculer les variations des six élémens de l'orbite elliptique, tantis que le nombre des coordonnées qu'il s'agit, en définitive, de déferminer, n'est que

de trois, ce qui donne au calculateur un travail double de celai quell devrait naturellement exécuter : et si déjà c'est là un grave reproche à faire à cette méthode, les difficultés de calculs qu'elle entraine s'augmentent encore, parce que les perturbations des coordonnées sont suppassées, en nombre et en grandeur, par celles de chacun des élémens elliptiques. Enfin, lorsque celles-ci sont ainsi calculées, il faut encore, nour chtenir les variations des Coordonnées de la planète, introduire dans les formules de son mouvement elliptique ces élémens corrigés de leurs variations, et les développer ensuite par le théorème de Taylor. Mais outre les longueurs de cette double opération, on est obligé, dans la détermination des inégalités des élémens, de pousser l'appreximation, relativement aux excentricités et aux inclinaisons, au-delà du degré qu'on veut obtenir dans les perturbations des coordonnées; enfin, cet inconvénient devient plus grand encore quand on passe au carré et aux puissances supérieures des forces perturbatrices, parce qu'il arrive alors que chacune des inégalités de ces coordonnées est composée d'un grand nombre de parties, et que les plus considérables proviennent sonvent de quantités qu'on aurait cru pouvoir négliger.

Cependant M. Hansen n'a pas cru ces raisons suffisantes pour rejeter entièrement l'emploi de la variation des constantes arbitraires; il a cherché seulement à éviter les inconvéniens que nous venons de signaler, et à réunir dans une même analyse les avantages particuliers aux deux méthodes d'intégration. Pour cela, il a pensé qu'il serait bon: d'introduire dans les formules du mouvement elliptique les expressions: des variations des élémens relatifs à cette hypothèse, avant de les avoirréduites en nombres, ce qui permettrait de réunir les diverses inégalités qui doivent se fondre les unes dans les autres, et simplifierait les formules. Mais pour que cette réduction pût s'opérer, il fallait que les expressions différentielles des variations des élémens elliptiques fussent introduites elles-mêmes dans les valeurs de la longitude, du rayon vecteur et de la latitude; or comme, par la théorie de la variation des constantes arbitraires, ces trois quantités doivent conserver la même forme dans le cas de l'orbite troublé et dans le cas de l'orbite elliptique, il en résulte que leurs expressions différentielles relatives aux constantes qu'elles renferment, et, par conséquent, les fonctions résultantes de la substitution précédente seront identiquement nulles. M. Hansen pare à cet inconvénient par un artifice dont l'effet est de distinguer le tems t introduit par les variations des élémens, de la même variable contenue dans les formules du mouvement elliptique. M. Hansen parvient ainsi à des expressions qui donnent, sous la forme la plus simple possible, les

valeurs différentielles de la longitude, du rayon vecteur et de la latitude, à une époque déterminée, dans l'orbite troublée, et il intêgre ensuite ces formules par la méthode des quadratures, procédé qui a sur le développement en série de la fonction perturbatrice le grand avantage de donner toutes les inégalités d'une planète dépendantes d'un argument déterminé, indépendamment de la grandeur des excentricités et des inclinaisons. Cette manière d'intégrer les formules du mouvement troublé avait été depuis long-tems indiquée par M. Poisson; on en avait fait l'application aux perturbations des petites planètes, mais il restait à l'appliquer aux planètes principales, et en particulier à la théorie de Jupiter et de Saturne, pour comparer les résultats ainsi obtenus à ceux qu'on avait trouvés par la méthode ordinaire d'approximation : cette tâche a été heureusement remplie par M. Hansen.

Une seconde innevation se fait remarquer dans les mémoires de cet astronome; elle lui appartient plus en propre encore que la première, et paraît comme l'idée capitale qui a dirigé ses recherches, car il y revient continuellement dans tons ses ouvrages. M. Hansen, au lieu de déterminer directement, comme l'ont fait jusqu'ici tons les géomètres qui se sont occupés des perturbations planétaires, les variations de la longitude vrale et du rayon vecteur, détermine les variations d'une quantité qui doit être substituée au moyen mouvement dans les formules du mouvement elliptique, les autres élémens de l'orbite devant être regardés comme invariables. De cette manière, toutes les variations de ces élémens, déterminées selon, la méthode ordinaire, se trouvent, pour ainsi dire, réunis en une seule, qui s'applique directement au moyen mouvement dans les formules du mouvement elliptique (*).

^(*) Sans doute il doit résulter de là, dans le calcul des perturbations de la longitude vraie, quelque avantage sons le rapport de la simplicité, sur la méthode qui consiste à introduire dans les formules qui la déterminent, les variations de tous les élémens de l'orbite elliptique; mais on ne conçoit pas pourquoi M. Hansen a pu préférer ce procédé, qui doit l'obliger à une nouvelle substitution de la variation de la longitude moyenne dans l'expression de la longitude vraie, pour en déduire sa valeur relative au mouvement troublé, à celui qui lui aurait donné directement les perturbations de cette longitude. Il m'a été impossible de trouver une raison suffisante de cette préférence dans les divers ouvrages de M. Hansen, et il serait nécessaire qu'il s'expliquât clairement à cét égard. J'ai peine à comprendre aussi pourquoi il a choisi la méthode d'intégration foudée sur la variation des constantes arbitraires, dont il avait lui-même signalé les inconvéniens, plutôt que celle qui donne directement, sous forme finie, les expressions de la longitude vraie du rayon vecteur et de la latitude, et qui semble s'adapter bien plus aisément au calcul des quadratures paraboliques. Le désir de présenter des formules nouvelles ne serait pour des formules nouvelles ne serait pour des formules un léges métités.

Quant aux perturbations du rayon vecteur, elles se déduisent au moyen d'une équation de condition très simple, et par la scule différentiation, des perturbations de la longitude supposées connues. Cette méthode a, comme je l'ai remarqué ailleurs, de l'avantage sur les formules de la Mécanique céleste, qui donnent les perturbations de la longitude au moyen de celles du rayon vecteur, parce que ces dernières étant beaucoup moins sensibles, et surtout beaucoup moins importantes pour les usages astronomiques que les premières, n'exigent pas qu'on pousse aussi loin les approximations.

Enfin, les formules qui donnent les perturbations de la latitude se rapprochent beaucoup de celles qui se rapportent à la longitude, et peuvent, à quelques légères différences près, être traitées de la même manière.

Dans son dernier mémoire, dont l'objet est de reproduire, par des considérations nouvelles, les mêmes formules auxquelles il est parvenu dans ses publications précédentes, M. Hansen annonce qu'il présentera incessamment l'application de ses formules aux perturbations planétaires causées par la résistance d'un milieu très rare, et notamment à celles de la comète à courte période de 1819. Il promet aussi d'offrir des modèles de nouvelles tables planétaires destinées à donner les longitudes et les latitudes des planètes réduites immédiatement au plan de l'équateur.

Formules qui déterminent les perturbations de la longitude, du rayon de vecteur et de la latitude d'une planète troublée par l'action d'une d'une planète.

1. Soient x, y, s, les trois coordonnées rectangulaires d'une plannète m; soient r, v, s, ses trois coordonnées polaires, c'est-à-dire sen rayon vecteur, sa longitude vraie et sa latitude, l'origine de toutes ses coordonnées étant au centre du Soleil. Soient x', y', s', r', v', s', les mêmes quantités relatives à la planète m'. Si pour abréger on fait

$$R = m' \left[ \frac{1}{\sqrt{(x'-x)^2 + (y'-y)^2 + (z'-z)^2}} - \frac{xx' + yy' + zx')}{r'^3} \right],$$

et  $\mu = 1 + m$ , la masse du Soleil étant prise pour unité, pour déterminer les mouvemens relatifs de m autour de cet astre, en aura

que la nonveauté, si elles n'avaient encore celui d'éne plus simples que les formules empluyées jusque-là.

Au reste, nous devons prévenir, une fois pour toutes, qu'en donnant ici une analyse exacte des travaux de M. Hausen sur la théorie des perturbations planétaires, nous n'un-tendons pas approuver, sans restriction, ni ses idées ni ses méthodes.

$$\frac{d^{2}x}{dt^{2}} + \frac{\mu x}{r^{3}} = \frac{dR}{dx},$$

$$\frac{d^{2}y}{dt^{2}} + \frac{\mu y}{r^{3}} = \frac{d}{dy},$$

$$\frac{d^{2}z}{dt^{2}} + \frac{\mu z}{r^{3}} = \frac{dR}{dz}.$$
(1)

Ces trois équations différentielles du second ordre ne peuvent s'intégrer, que par les méthodes d'approximation. Il y en a deux principales; la première consiste à combiner ces équations de manière à en tirer les expressions du rayon vecteur, de la longitude et de la latitude, en fonction de R et de ses différences partielles, et à intégrer ensuite ces expressions, soit par les développemens en séries ordonnées par rapport aux excentricités et aux inclinaisons, soit par le procédé des quadratures paraboliques. Cette méthode est la plus simple que l'on puisse employer lorsque l'on veut déterminer toutes les inégalités sensibles d'une planète. La seconde méthode, sans contredit l'une des plus ingénieuses conceptions des géomètres modernes, consiste à regarder les actions des planètes les unes sur les autres, qui sont en général peu considérables relativement à l'action du Soleil, comme de très petites forces qui ne font qu'altérer à chaque instant les élémens de l'orbite elliptique qui aurait lieu en vertu de la force principale, en sorte que l'orbite de la planète dans le mouvement troublé est encore une ellipse; mais les élémens de cette courbe varient continuellement, et l'ellipse troublée est à chaque instant osculatrice de celle qui aurait lieu si les forces perturbatrices venaient en cet instant à cesser leur action. D'après cela, on commence par intégrer les équations précédentes dans le cas où la fonction R est nulle, et l'on déternsine ensuite les variations de chacun des élémens de l'orbite troublée, de manière à satisfaire, par les mêmes intégrales, aux équations complètes (1). Mais comme les constantes introduites par l'intégration sont au nombre de six, et qu'il n'y a que trois équations à satisfaire, le problème est indéterminé, et l'on peut s'imposer trois nouvelles conditions à remplir ; c'est ce que l'on fait de manière à obtenir des résultats très simples, en exigeant que la nouvelle orbite soit osculatrice de la première. En effet, en vertu de cette condition, non-seulement les valeurs des trois coordonnées x, y, z, mais encore celles de leurs trois différentielles dx, dy, dz, sont les mêmes dans l'orbite elliptique et dans l'orbite troublée; en sorte que toute équation finie ou différentielle du premier ordre, appartenant à la première orbite, a encore lieu relativement à la seconde, et que les différentielles du deuxième ordre seulement seront différentes dans les deux hypothèses. Il suit de là que les équations sinies du monvement elliptique peuvent être dissérentiées, soit en regardant les élémens de l'orbite comme constans, ou en les traitant comme variables, et il en résulte trois nouvelles équations de condition entre les variations des élémens elliptiques, qui, jointes à celles qui proviennent de la condition de satisfaire aux équations (1), suffirent pour les déterminer.

On peut aisément déterminer par cette méthode les variations de chacun des élémens de l'orbite elliptique, et les géomètres ont donné à leurs expressions différentes formes qui ont chacune des avantages particuliers. La plus remarquable sans doute est celle qui donne les variations des élémens elliptiques en fonction des différences partielles de la fonction perturbatrice, relatives à ces élémens, multipliées par des fonctions de ces mêmes élémens, indépendantes du tems. Les expressions des variations différentielles des élémens du mouvement elliptique sont employées spécialement sous cette forme pour déterminer les inégalités séculaires de ces élémens, et les inégalités périodiques du mouvement d'une planète qui deviennent sensibles par le rapport qui existe entre son moyen mouvement et celui de la planète perturbatrice. Mais ici nous choisirous les expressions qui donnent les variations des élémens elliptiques au moven des différences partielles de la fonction perturbatrice, prises par rapport aux trois coordonnées polaires de la planète troublée, parce que leur emploi nous conduira plus directement aux formules auxquelles nous voulons parvenir.

2. Si dans le mouvement elliptique on nomme a le demi-grand axe, e l'excentricité de l'orbite de m, a et s les longitudes du périhélie et de l'époque, pour déterminer les variations de ces quantités produites par l'action de m', on aura les formules suivantes:

$$d \cdot \frac{1}{a} = -\frac{2}{\mu} \left( dv \frac{dR}{dv} + dr \frac{dR}{dr} \right),$$

$$de = \frac{andt}{\mu \sqrt{1 - e^2}} \left[ 2 \cos \left( v - u \right) + e + e \cos^2 \left( v - u \right) \right] \frac{dR}{dv},$$

$$+ \frac{a^2 n dt \sqrt{1 - e^2}}{\mu} \sin \left( v - u \right) \frac{dR}{dr},$$

$$edu = \frac{andt}{\mu \sqrt{1 - e^2}} \left[ 2 + e \cos \left( v - u \right) \right] \sin \left( v - u \right) \frac{dR}{dv}$$

$$- \frac{a^2 n dt \sqrt{1 - e^2}}{\mu} \cos \left( v - u \right) \frac{dR}{dr},$$

$$dt = \left[ 1 - \sqrt{1 - e^2} \right] du - \frac{andt}{\mu} r \left( \frac{dR}{dr} \right).$$

Enfin, Péquation  $a^2n^2 = \mu$  donne  $\frac{dn}{n} = -\frac{3}{2}\frac{da}{a}$ ; par conséquent,

$$dn = -\frac{3an}{\mu} \left( dv \frac{dR}{dv} + dr \frac{dR}{dr} \right). \quad (2)$$

Au lieu des élémens de l'orbite elliptique on emploie quelquefois dans la théorie des perturbations planétaires des fonctions de ces élémens, telles que les quantités e sin  $\theta$ , e cos  $\theta$ , tang  $\varphi$  sin  $\theta$ , tang  $\varphi$  cos  $\theta$ , et il est évident qu'on aura très aisément les valeurs différentielles de ces fonctions du moment que celles des élémens primitifs auxquels on veut les substituer seront données. On peut faire prendre ainsi aux expressions des variations des élémens du mouvement elliptique différentes formes, selon le choix que l'on fera des six constantes arbitraires que l'intégration introduit dans les formules de ce mouvement. Les plus simples que l'on puisse obtenir sont celles qui se rapportent au cas où l'on prend pour constantes arbitraires les valeurs des trois coordonnées x, y, zet de leurs trois différences  $\frac{dx}{dt}$ ,  $\frac{dy}{dt}$ ,  $\frac{dz}{dt}$ , qui répondent à une époque déterminée, par exemple, à l'instant où l'on a t = r. On pourrait par analogie, au lieu de ces six quantités, choîsir pour arbitraires les trois coordonnées polaires r, v, s de la planète m relatives à la même époque, et leurs trois différences premières  $\frac{dr}{dt}$ ,  $\frac{dv}{dt}$ ,  $\frac{ds}{dt}$ , et il serait facile sans doute d'exprimer les variations de ces six quantités de la même manière que celle des élémens ordinaires du mouvement dans l'ellipse. Nous allons considérer sous ce point de vue la théorie des variations des constantes arbitraires.

Les coordonnées r et v de la planète m sont données par les formules du mouvement elliptique en fonction du moyen mouvement, du demi-grand axe, de l'excentricité et des deux constantes qui déterminent les longitudes du périhélie et de l'époque. En serte qu'on a généralement:

$$v = \text{fonct.}(nt, e, \epsilon, \omega), r = \text{Fonct.}(nt, a, e, \epsilon, \omega).$$

Soient  $\lambda$  et  $\ell$  les valeurs de la longitude vraie et du rayon vecteur de m relatives à l'instant  $\tau$ , c'est-à-dire ce que deviennent  $\nu$  et r lorsque dans les formules précédentes on fait  $t = \tau$ . On aura ainsi :

 $\lambda = \text{fonct.}(Rr, e, \epsilon, \omega)$  et  $g = \text{Fonct.}(Rr, a, e, \epsilon, \omega)$ 

Les deux quantités  $\lambda$  et  $\ell$  seront deux fonctions connues des éléments elliptiques qui ne contiendront pas explicitement le tems  $\ell$ , et qui par consequent ne varieront qu'autant que ces quantités elles mêmes varieraient. En les différentiant donc par rapport aux élémens qu'ils renferment, et en observant que l'on a  $\frac{d\lambda}{\tau dn} = \frac{d\lambda}{n d\tau}$  et  $\frac{d\varrho}{\tau dn} = \frac{d\varrho}{n d\tau}$ , on trouvera :

$$\frac{d\lambda}{dt} = \frac{d\lambda}{ndr} \frac{\tau dn}{dt} + \frac{d\lambda}{de} \frac{de}{dt} + \frac{d\lambda}{ds} \frac{ds}{dt} + \frac{d\lambda}{dw} \frac{dw}{dt},$$

$$\frac{d\xi}{dt} = \frac{d\xi}{ndr} \frac{\tau dn}{dt} + \frac{d\xi}{da} \frac{da}{dt} + \frac{d\xi}{de} \frac{de}{dt} + \frac{d\xi}{ds} \frac{ds}{dt} + \frac{d\xi}{dw} \frac{dw}{dt}.$$
(3)

Il est bon de remarquer que lorsqu'on ne considère, comme nous le faisons en ce moment, que les quantités du premier ordre par rapport à la force perturbatrice, les différences  $\frac{d\lambda}{ndr}$ ,  $\frac{d\lambda}{de}$ , etc.,  $\frac{d\varrho}{ndr}$ ,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc.,  $\frac{d\varrho}{de}$ , etc

On peut observer encore que si dans les seconds membres des équations (4) on substitue  $\tau$  à la place de t, ce qui change  $\lambda$  et  $\ell$  en  $\ell$  et  $\ell$ , les premiers membres doivent se réduire à zéro. Puisque en effet  $\ell$  et  $\ell$  étant des fonctions des coordonnées  $\ell$ ,  $\ell$  et  $\ell$  qui ne contiennent aucun des élémens de l'orbite  $\ell$ , en ne considérant que la variation des constantes, on a par la théorie de ces variations  $\ell$  o et  $\ell$  o et  $\ell$  o et  $\ell$  o et  $\ell$  o et  $\ell$  on substitue leurs valeurs après avoir changé  $\ell$  en  $\ell$  dans  $\ell$  et  $\ell$ , les seconds membres des équations précédentes soient identiquement nuls.

Supposons maintenant que dans les équations (3) on substitue pour  $\frac{d\lambda}{dr}$ ,  $\frac{d\lambda}{de}$ , etc., leurs valeurs relatives au mouvement elliptique, et pour  $\frac{dn}{dt}$ ,  $\frac{de}{dt}$ , etc., leurs valeurs données par les formules (2), et qu'on les intègre ensuite, les quantités résultantes seront les variations que subissent  $\lambda$  et e en passant de l'hypothèse elliptique à l'hypothèse du mouvement troublé. Or, par les formules du mouvement dans l'ellipse, on aura:

$$\frac{dv}{ds} = \frac{dv}{ndt} = \frac{\left[1 + e\cos(v - u)\right]^{c}}{\left(1 - e^{a}\right)^{\frac{3}{2}}}, \qquad \frac{dr}{ds} = \frac{dr}{ndt} = \frac{ae\sin(v - u)}{\sqrt{1 - e^{a}}},$$

$$\frac{dv}{ds} = 1 - \frac{dv}{ndt} = 1 - \frac{\left[1 + e\cos(v - u)\right]^{a}}{\left(1 - e^{a}\right)^{\frac{3}{2}}}, \qquad \frac{dr}{du} = \frac{ae\sin(v - u)}{\sqrt{1 - e^{a}}},$$

$$\frac{dv}{de} = \frac{\left[2 + e\cos(v - u)\right]\sin(v - u)}{1 - e^{a}}, \qquad \frac{dr}{de} = -a\cos(v - u).$$

On aura donc, en changeant # en + dans ces formules:

$$\frac{d\lambda}{ndr} = \frac{d\lambda}{di} = \frac{\left[1 + e\cos(\lambda - e)\right]^{2}}{\left(1 - e^{2}\right)^{\frac{1}{2}}}, \qquad \frac{d\varrho}{ndr} = \frac{d\varrho}{di} = \frac{e\sin(\lambda - e)}{\sqrt{1 - e^{2}}},$$

$$\frac{d\lambda}{de} = 1 - \frac{\left[1 + e\cos(\lambda - e)\right]^{2}}{\left(1 - e^{2}\right)^{\frac{1}{2}}}, \qquad \frac{d\varrho}{de} = \frac{ae\sin(\lambda - e)}{\sqrt{1 - e^{2}}},$$

$$\frac{d\lambda}{de} = \frac{\left[2 + e\cos(\lambda - e)\right]\sin(\lambda - e)}{1 - e^{2}}, \qquad \frac{d\varrho}{de} = -e\sin(\lambda - e),$$

On a d'ailleurs  $\frac{dr}{da} = \frac{r}{a}$ , et par conséquent  $\frac{d\ell}{da} = \frac{\ell}{a}$ .

En substituant ces valeurs dans les équations (3), on pourra leur donner cette forme:

$$\frac{d\lambda}{dt} = \frac{d\lambda}{ndr} \left[ \frac{dn}{dt} + \frac{ds}{dt} - \frac{d\sigma}{dt} + \frac{e \sin(\lambda - \sigma)}{a\sqrt{1 - e^{\lambda}}} \left( 1 + \frac{1}{1 - e^{\lambda}} \frac{e}{a} \right) \frac{de}{dt} \right] + \frac{1}{\sqrt{1 - e^{\lambda}}} \frac{e^{\lambda}}{a^{\lambda}} \cdot \frac{d\sigma}{dt}, \qquad (4)$$

$$\frac{d}{dt} = \frac{e}{a} \frac{da}{dt} + \frac{de}{ndr} \cdot \left[ \frac{dn}{dt} + \frac{ds}{dt} - \frac{d\sigma}{dt} - \frac{\sqrt{1 - e^{\lambda}}\cos(\lambda - \sigma)}{e \sin(\lambda - \sigma)} \frac{de}{dt} \right].$$

Il ne restera plus qu'à substituer dans ces équations, à la place des variations différentielles  $\frac{da}{dt}$ ,  $\frac{da}{dt}$ , etc., leurs valeurs (2), et l'on aura les variations différentielles de  $\lambda$  et  $\epsilon$  exprimées au moyen des différences de la fonction R prises par rapport aux coordonnées  $\nu$  et r et multipliées par des fonctions de ces variables.

Nous remarquerons que si l'on prend pour les élémens du mouvement elliptique qu'en est libre de choisir à volenté, les trois coordonnées v, r, s de m à une époque donnée, et leurs trois différences premières  $\frac{dv}{dt}$ ,  $\frac{dr}{dt}$ ,  $\frac{ds}{dt}$ , qu'on les introduise dans les formules du mouvement ellip-

tique, et que suivant les principes de la variation des constantes, on détermine les variations différentielles de ces six arbitraires, on doit arriver directement aux formules qui résultent des diverses substitutions que nous venous d'indiquer. C'est en effet ce que s'est proposé M. Hansen dans son dernier Mémoire; en reprenant les formules de Lagrange relatives à la variation des constantes arbitraires, et en choisissant les valeurs des six quantités v, r, s,  $\frac{dv}{dt}$ ,  $\frac{dr}{dt}$ ,  $\frac{ds}{dt}$  à une époque donnée pour les élèmens du mouvement elliptique, il est parvenu à exprimer les variations de ces quantités par des formules qui comprennent les formules (4). Mais comme cette recherche n'est comme on voit que de simple curiosité, nous ne nous v arrêterons pas ici.

3. Avant d'effectuer dans les équations (4) la substitution que nous avons indiquée, il sera bon de faire sur ces formules quelques observations qui pourront nous être très utiles dans la suite.

Nous observerons d'abord que le terme  $\tau$   $\frac{dn}{dt}$  que renferment les formules (4) n'entre pas ordinairement dans les formules du mouvement troublé, parce que l'expression de la variation de la longitude : de l'époque contenant un terme égal au signe près, celui dont il s'agit disparaît dans l'expression de la variation de la longitude moyenne, et par conséquent dans celle de la longitude vraie et du rayon vecteur relatifs au mouvement troublé.

En effet dans les formules du mouvement elliptique, le moyen mouvement nt étant toujours accompagné de la constante : , on aura identiquement :

$$nt + \epsilon = fndt + ftdn + fd\epsilon$$
;

Et comme le terme ftdn est détruit par le terme semblable mais de signe contraire contenu dans fdi, on pourra en faire abstraction, pourvu qu'on ait soin de déterminer convenablement la valeur de cette dernière intégrale. On aura donc simplement ainsi:

c'est-à-dire qu'il sussit de remplacer nt par s'ndt dans les sormules du mouvement elliptique, et de substituer ensuite à la place des élémens de l'orbite elliptique leurs valeurs augmentées de leurs variations, pour avoir des sormules qui conviennent au mouvement troublé, et c'est ainsi que cela se pratique ordinairement. Mais dans le cas qui nous occupe, le terme rdn ne disparaît pas de l'expression de da, et comme l'expression

de d contient le terme — tdn, il en résulte dans  $\frac{d\lambda}{dt}$  le terme

$$(\tau - t) \frac{dn}{dt},$$

lequel étant multiplié par dt et intégré par parties, produit dans l'expression de  $\lambda$  relative au mouvement troublé les termes suivans :

$$\int ndt + (\tau - t)n.$$

Si l'on suppose maintenant  $\tau = t$ , on voit que le dernier terme disparaît et que le premier est celui qui résulte de la supposition que dans les formules du mouvement elliptique on a substitué f ndt à nt pour les appliquer au mouvement troublé.

On voit donc qu'en intégrant par rapport au tems t les formules (4) et en substituant ensuite t à la place de  $\tau$ , elles donneront les expressions de la longitude vraie et du rayon vecteur relatives au mouvement troublé; mais il faut remarquer en même tems que si l'on changeait  $\tau$  en t dans les formules différentielles (4) avant d'effectuer l'intégration, les valeurs qui en résulteraient ne seraient point celles de  $\frac{dv}{dt}$ , et de  $\frac{dr}{dt}$  qui conviénnent au mouvement troublé, parce qu'elles ne rensermeraient pas les termes provenant de la supposition qu'on a substitué f ndt à la place de nt dans les formules du mouvement elliptique. Au reste, nous reviendrons plus bas sur ce point important.

Il existe entre les variations différentielles de  $\lambda$  et de  $\rho$  une relation qu'il est bon de connaître, et dont nous ferons un grand usage dans ce qui va suivre. En effet, on a dans l'orbite elliptique

$$r^a du = dt \sqrt{a\mu (1-e^a)}$$
.

En changeant dans cette équation t en r, on aura donc

$$e^{a}da = de \sqrt{a\mu (i-e^{i})}$$

Cette équation étant une différentielle du premier ordre, elle doit encore exister dans le cas du mouvement troublé, en la différentiant logarithiquement, on aura donc alors:

$$2 \frac{de}{e^{dt}} + \frac{d \cdot \left(\frac{d\lambda}{dt}\right)}{\left(\frac{d\lambda}{d\tau}\right)} = \frac{d \cdot \sqrt{a\mu \left(1 - e^{\lambda}\right)}}{\sqrt{a\mu \left(1 - e^{\lambda}\right)}}.$$
 (5)

Si l'on substitue dans cette équation les valeurs précédentes de  $\frac{de}{dt}$  et de  $\frac{d\lambda}{dt}$ , et qu'on observe que

l'on a  $\frac{dn}{n} = -\frac{3}{2} \frac{da}{a}$ , on verra que ces valeurs y satisfont en effet. La formule (5) peut servir à déterminer les inégalités du rayon vecteur au moyen de celles de la longitude vraie supposées connues , et je l'ai employée à cet usage dans le Livre II de la Théorie analytique du Système du Monde.

4. Maintenant, au lieu d'effectuer dans les équations (4) la substitution des valeurs de  $\frac{da}{dt}$ ,  $\frac{dn}{dt}$ , etc., nous substituerons aux deux quantités  $\lambda$  et  $\rho$  d'autres constantes arbitraires fonctions de relies-ci, mais qui ont l'avantage de rendre plus simples les formules, et qui sont comme la base de la nouvelle théorie des inégalités planétaires que nous analysons.

D'abord, au lieu du rayon vecteur r, M. Hansen introduit dans ses recherches le logarithme de ce rayon qu'il désigné par lr. De même par analogie, au lieu des constantes a et  $\ell$ , il emploie leurs logarithmes la et  $l_{\ell}$ . Cette substitution n'a rien que de très simple, et elle peut s'opérer immédiatement dans les formules précédentes, en observant qu'on a généralement d.  $\log r = \frac{dr}{r}$ .

Nous supposerons ensuite, avec M. Hansen, que la longitude vraie dans l'orbite troublée soit exprimée en fonction de la variable z, de la même manière que la longitude vraie dans l'orbite elliptique l'est eu fonction du tems. Ou bien, en d'autres termes, que z soit une quantité variable déterminée par cette condition, qu'étant substituée à la place du tems é dans l'expression de « relative à l'orbite elliptique, elle donne immédiatement la longitude vraie dans l'hypothèse du mouvement troublé. En sorte donc que les perturbations de m seront toutes immédiatement applicables à la longitude moyenne, lès autres étémens de Ferbite elliptique devant être regardés comme invariables.

Quant au reyon vecteur, on peut regarder r ou le comme function de la vav et des constantes u, e, e et e, où bien comme function de la variable z et d'une nouvelle constante s, celle-ci étant déterminée par l'équation

$$d\beta = \frac{dr}{da} da + \frac{dr}{dc} dc + \frac{dr}{ds} ds + \frac{dr}{da} da,$$

dr dr, etc., désignant les différences partielles de r prises par rapport aux constantes a, e, s, e, en tant que ces constantes ne sont pas conternues dans v. On aura dosse ainsi:

$$\log r = \text{Fonct.}(z) + \beta_*$$

Maintenant, si à la place de t on substitue  $\tau$  dans les formules précédentes,  $\nu$  et r se changeront respectivement en  $\lambda$  et  $\xi$ ; nommons  $\zeta$  ce que devient s par cette substitution,  $\beta$  étant une quantité constante, on aura

Ces deux équations donneront  $\lambda$  et log  $\rho$  en fonction de  $\zeta$  et de  $\beta$ , et réciproquement on pourra en tirer les valeurs de ces deux quantités en fonction de  $\lambda$  et de  $\rho$ .

5. Avant d'aller plus loin, il sera à propos de faire ici une observation propre à éclairer le but que nous nous proposons d'atteindre: Nous avons dit que d'après la théorie de la variation des constantes arbitraires, toute équation différentielle du premier ordre dans le mouvement elliptique subsistait encore dans le mouvement troublé. Soit done

une équation quelconque qui a lieu dans l'hypothèse elliptique, la différentielle de cette équation devra être identiquement la même, soit qu'on y regarde a, e, e, comme constantes, soit qu'on y fasse varier ces quatre élémens. En désignant donc par do la partie de la différentielle de a, résultante de la variation des constantes, on aura

Mais si l'on se borne à ronsidérer les quantités dépendantes de la première puissance des forces perturbatrices pour étendre l'équation (a) au mouvement troublé, il fant substituer f ndt à la place de nt et augmenter les constantes a, e, s et s' de leurs variations déterminées par les formules (2), en ne conservant que le premier terme du déve-

loppement de la fonction qui en résultera; c'est-à-dire que si l'on désigne par l'placé devant une fonction quelconque des élémens elliptiques, la variation finie de cette fonction résultante de celle des élémens, en se bornant à la première puissance des masses, on aura

$$\delta \varphi - \frac{d\varphi}{ndt} \int \delta n dt = \frac{d\varphi}{da} \delta a + \frac{d\varphi}{de} \delta e + \frac{d\varphi}{dt} \delta_1 + \frac{d\varphi}{d\theta} \delta_{\theta}. \quad (b)$$

Cette équation donnera la valeur finie de la variation de la fonction o due à l'action des forces perturbatrices.

On voit maintenant que pour passer de l'équation (a) à l'équation (b), c'est-à-dire pour obtenir la valeur de  $\delta \phi - \frac{d\phi}{ndt} \int ndt$ , il faudra intégret l'équation (a), en y regardant comme variable le tems t contenu dans les valeurs des différentielles da, de, da, ds, et regardant comme constant colai qui est contenu dans les différences  $\frac{d\phi}{da}$ ,  $\frac{d\phi}{de}$ ,  $\frac{d\phi}{ds}$ . Et réciproquement, pour avoir la différentielle de  $\delta \phi$ , il faudra ne faire varier que le tems t introduit par les valeurs de  $\delta n$ ,  $\delta a$ ,  $\delta e$ , etc., et regarder comme constant celai qui provient de  $\frac{d\phi}{ndt}$ ,  $\frac{d\phi}{da}$ ,  $\frac{d\phi}{de}$ , etc.

Supposons maintenant qu'on désigne par © ce que devient  $\phi$  lorsqu'on y change t en  $\tau$ ; comme la fonction  $\Phi$  est composée absolument de la même manière relativement aux élémens a, e,  $\iota$ ,  $\omega$  et à la quantité  $\tau$ , que  $\phi$  l'est par rapport aux élémens a, e,  $\iota$ ,  $\omega$  et à la variable t, on aux d'après ce qui précède, dans le cas du mouvement troublé,

$$d\Phi = \frac{d\Phi}{ade} \frac{\tau dR}{dt} + \frac{d\Phi}{da} da + \frac{d\Phi}{de} de + \frac{d\Phi}{dt} ds + \frac{d\Phi}{da} dw;$$

et comme  $\Phi$  est ici une fonction donnée de  $\tau$ , tandis que les différentielles des élémens da, dc, etc., contiennent seulement le tems t, on aura, en intégrant relativement à cette variable, la valeur finie de la fonction  $\Phi$  qui convient au mouvement troublé; on a vu que le premier terme produisait dans l'expression de  $\Phi$  la terme de  $\frac{dq}{nd\tau}$   $\int dndt$ , on aura donc évidemment

$$\int \frac{d\varphi}{dt} dt = \int \frac{d\Phi}{dt} dt,$$

pour ve qu'après l'intégration dans le second membre de cette équation on change  $\tau$  en L

Il n'est pas nécessaire sans doute d'insister beaucoup sur le motif de cette substitution de la quantité r à la place de la variable t. En effet, on voit clairement que lorsque dans l'équation (a) on aura remplacé da, de, de, etc., par leurs valeurs, et qu'on aura fait les réductions nécessaires, la différentielle de la fonction é se trouvera exprimée au moyen des différences de la fonction perturbatrice multipliées par des coefficiens qui sexont fonction du tems t, et dans lesquels cette variable, introduite par les valeurs différentielles des élémens elliptiques, se trouvera confondue avec celle qui provient des différences de la fonction  $\phi$ , relatives à ces mêmes élémens. L'intégration ne serait donc pas possible sous cette forme, et pour la rendre praticable il fallait distinguer, dans les coefficiens dont il s'agit, le tems s'introduit de ces deux manières différentes; c'est ce qu'on a fait en considérant, comme nous l'avons indiqué n° 2, les fonctions à et e qui représentent les valeurs de la longitude et du rayon vecteur, qui se rapportent au toms +, au lieu de la longitude et du rayon vecteur, relatifs à un instant indéterminé.

6. Reprenons maintenant les áquations (6). De ces équations on tire

$$\zeta = \varphi(\lambda),$$
  
 $\beta = \psi(\lambda) + l(c),$ 

φ et ψ représentant deux fonctions donnces,

Si l'on différentie successivement ces équations par rapport à  $\epsilon$  et par rapport à  $\tau$ , on aura

$$\frac{d\zeta}{dt} = \frac{d\zeta}{d\lambda} \cdot \frac{d\lambda}{dt}, \qquad \frac{d\zeta}{dt} = \frac{d\zeta}{d\lambda} \cdot \frac{d\lambda}{d\tau},$$

$$\frac{d\beta}{dt} = \frac{d\beta}{d\lambda} \cdot \frac{d\lambda}{dt} + \frac{d \cdot l_{\xi}}{dt},$$

$$\frac{d\beta}{d\tau} = \frac{d\beta}{d\lambda} \cdot \frac{d\lambda}{d\tau} + \frac{d \cdot l_{\xi}}{d\tau}.$$

Si l'on élimine  $\frac{d\zeta}{d\lambda}$ ,  $\frac{d\beta}{d\lambda}$  entre ses équations, on aura les deux suivantes :

Joh Pon tire

$$\frac{\left(\frac{d\hat{s}}{d\hat{t}}\right)}{\left(\frac{d\hat{\zeta}}{d\tau}\right)} = \frac{\left(\frac{d\hat{t}}{d\lambda}\right)}{\left(\frac{d\lambda}{d\tau}\right)},$$

$$\left(\frac{d\hat{\beta}}{d\hat{t}}\right) - \left(\frac{d\hat{\beta}}{d\tau}\right) \frac{\left(\frac{d\hat{\zeta}}{d\hat{t}}\right)}{\left(\frac{d\hat{\zeta}}{d\tau}\right)} = \frac{\left(\frac{d\cdot\hat{t}\xi}{d\hat{s}}\right)\left(\frac{d\lambda}{d\tau}\right) - \left(\frac{d\cdot\hat{t}\xi}{d\tau}\right)\left(\frac{d\lambda}{d\hat{t}}\right)}{\left(\frac{d\lambda}{d\tau}\right)}.$$

Ces deux équations feront connaître les quantités  $\zeta$  et  $\beta$  en fonction de  $\lambda$  et de I. g, qu'on doit regarder comme des quantités connues. Mais il est plus commodé, comme on le verra plus loin, d'employer, au lieu de la première des équations précédentes, se différentielle prise par rapport à  $\tau$ . On aura ainsi

$$d \cdot \frac{\left(\frac{d\zeta}{dt}\right)}{\left(\frac{d\zeta}{d\tau}\right)} = \frac{\left(\frac{d^3\lambda}{d\tau dt}\right)\left(\frac{d\lambda}{d\tau}\right) - \left(\frac{d^3\lambda}{d\tau^2}\right)\left(\frac{d\lambda}{dt}\right)}{\left(\frac{d\lambda}{d\tau}\right)};$$

nous ferons dans la suite, pour abréger,

$$T = \frac{\left(\frac{d^{\lambda}\lambda}{drdt}\right)\left(\frac{d\lambda}{dr}\right) - \left(\frac{d^{\lambda}\lambda}{idr^{\lambda}}\right)\left(\frac{d\lambda}{ds}\right)}{\left(\frac{d\lambda}{dr}\right)},$$

$$S = \frac{\left(\frac{d^{\lambda}k}{dt}\right)\left(\frac{d\lambda}{ds}\right) - \left(\frac{d^{\lambda}k}{idr}\right)\left(\frac{d\lambda}{dt}\right)}{\left(\frac{d\lambda}{dr}\right)}.$$

Ainsi, Tet S seront des fonctions de  $\lambda$  et de l(e) qu'il s'agira d'abord d'exprimer de la manière la plus simple et la plus propre à en facti-liter le développement et le calcul numérique.

7. Commençons par la première; on a

$$\frac{d\lambda}{dt} = \frac{1}{n} \left[ \frac{rdn}{dt} + \frac{dt}{dt} - \frac{d\omega}{dt} + \frac{\sin(\lambda - \omega)}{a\sqrt{1 - c^2}} \left( 1 + \frac{\epsilon}{a(1 - c^2)} \frac{dc}{dt} + \frac{1}{\sqrt{1 - c^2}} \frac{\epsilon^2}{a^2} \cdot \frac{dc}{dt} \right].$$

La constante r n'étant pas contenue dans les variations dn, de, etc., des élémens elliptiques, en différentiant par rapport à r l'équation précédente, il ne faudra faire varier que à et e, en observant d'ailleurs que Pon a

$$d \cdot \frac{\left(\frac{d\lambda}{di}\right)}{\left(\frac{d\lambda}{dr}\right)},$$

on trouvers sinsi

$$\mathbf{T} = \frac{dn}{ndt} + \frac{1}{1-e^{\lambda}} \left\{ e + \frac{2[e + \cos(\lambda - e)]}{1+e\cos(\lambda - e)} \right\} \cdot \frac{de}{dt} + \frac{2\sin(\lambda - e)}{1+e\cos(\lambda - e)} \cdot e^{\frac{de}{dt}}.$$

Quant à la valeur de S, nous observerons qu'on a  $d.l_{\xi} = \frac{d\xi}{2}$ . En

substituent donc  $\frac{\xi d \cdot l_{\xi}}{dt}$  à la place de  $\frac{d\xi}{dt}$  dans la seconde des equa-

tions (7), et en y ajoutant la valeur précédente de  $\frac{\overline{dt}}{d\lambda}$ , multipliée

per 
$$\frac{d.l_{\xi}}{dr}$$
, on aura

$$S = \frac{d \cdot la}{dt} - \frac{1}{1 - e^{-t}} \left\{ e + \frac{e + \cos(\lambda - e)}{1 + \cos(\lambda - e)} \right\} \cdot \frac{de}{dt} - \frac{\sin(\lambda - e)}{1 + e\cos(\lambda - e)} \cdot e^{\frac{de}{dt}}$$

Ces deux expressions mettent en évidence une relation remarquable qui existe entre les quantités T et S, mais qui n'est qu'une conséquence de l'équation de condition (5) que nous avons trouvée, n° 3, entre les variations différentielles de à et de g. En effet, si à la première on ajoute le double de la seconde, en observant qu'on a  $\frac{dn}{B} = -\frac{3}{2} \frac{da}{a}$ , on trouve.

$$2 S + T = \frac{1}{2} \frac{da}{adt} - \frac{1}{1 - e^2} \frac{de}{dt} = \frac{d. \sqrt{a(1 - e^2)}}{dt \sqrt{a(1 - e^2)}}.$$

D'après les valeurs précédentes de da et de de, on a,

$$\frac{d \cdot \sqrt{a(1-e^2)}}{\sqrt{a(1-e^2)}} = \frac{andt}{\mu \sqrt{1-e^2}} \cdot \frac{dR}{dv};$$

On aura donc
$$2S + T = \frac{an}{\mu \sqrt{1-e^2}} \cdot \frac{dR}{d\nu}, \quad (8)$$

ou bien, en remettant pour S et T leurs valeurs.

$$2\frac{d \cdot l_{\xi}}{dt} - 2\frac{\left(\frac{dl_{\xi}}{d\tau}\right)}{\left(\frac{d\zeta}{d\tau}\right)} \left(\frac{d\zeta}{dt}\right) = \frac{an}{\mu \sqrt{1 - e^{2}}} \cdot \frac{dR}{dv} - \frac{d \cdot \left(\frac{d\zeta}{dt}\right)}{\left(\frac{d\zeta}{d\tau}\right)}; (g)$$

équation d'où l'on conclura les perturbations du rayon vecteur  $\epsilon$ , au moyen de celles de la quantité  $\zeta$ , supposées connues. Cette équation s'accorde parfaitement avec l'équation (5), n° 3, comme il est facile de le vérifier.

Nous pouvons maintenant réduire à leur forme la plus simple les quantités T et S, en substituant dans leurs expressions à la place de da, de, edu leurs valeurs données n° 2: cette substitution faite, les valeurs de T et S, après quelques réductions, deviennent:

$$T = \frac{an}{\mu\sqrt{1-e^2}} \cdot \frac{dR}{d\nu}$$

$$-\frac{2an}{\mu\sqrt{1-e^2}} \left\{ 1 - \frac{\ell}{r} \cos(\nu - \lambda) + \frac{\ell}{a(1-e^2)} \left[ 2 - \cos(\nu - \lambda) \right] \right\} \frac{dR}{d\nu}$$

$$+ \frac{2an}{\mu\sqrt{1-e^2}} \cdot \frac{\ell}{r} \sin(\nu - \lambda) \cdot r \frac{dR}{dr},$$

$$S = \frac{an}{\mu\sqrt{1-e^2}} \left\{ 1 - \frac{\ell}{r} \cos(\nu - \lambda) + \frac{\ell}{a(1-e^2)} \left[ 1 - \cos(\nu - \lambda) \right] \right\} \frac{dR}{d\nu}$$

$$- \frac{an}{\mu\sqrt{1-e^2}} \cdot \frac{\ell}{r} \sin(\nu - \lambda) \cdot r \frac{dR}{dr}.$$

Si l'on ajoute à la première de ces valeurs le double de la seconde, on retrouve l'équation (8) à laquelle nous sommes parvenus dans le n° précédent; ce qui peut servir de vérification à l'exactitude des calculs.

8. Si l'on multiplie par de l'expression de T, et qu'on l'intègre ensuite,

on aura  $f T d\tau = \frac{\left(\frac{d\zeta}{dt}\right)}{\left(\frac{d\zeta}{d\tau}\right)}$ , et la constante arbitraire qu'il faut joindre à

cette intégrale doit être une fonction de t, déterminée par la condition qu'en changeant  $\tau$  en t, l'intégrale s'évanouisse. En effet, par cette substitution,  $\lambda$  se change en  $\nu$ ; et l'on a  $\frac{d\xi}{dt} = \frac{d\xi}{d\nu} \cdot \frac{d\nu}{dt}$ ; or,  $\frac{d\nu}{dt}$  est la

partie de la valeur de la différentielle de  $\nu$  qui vient de la variation des constantes, laquelle doit être nulle, n° 2, d'après la théorie de ces variations, puisque les différentielles premières des trois coordonnées de la planète m conservent la même forme, soit que les élémens elliptiques soient regardés comme constans ou traités comme variables,

on aura donc 
$$\frac{dv}{dt}$$
 = 0, et par conséquent  $\frac{d\xi}{dt}$  ainsi que  $\frac{\left(\frac{d\xi}{dt}\right)}{\left(\frac{d\xi}{d\tau}\right)}$  so-

rout nuls forsqu'on y aura changé r en &

Lorsque les valeurs de s'Tdr et de S seront ainsi calculées, on les substituera dans les équations (7), et l'en aura, par une nouvelle intégration relative au teme e les valeurs des quantités & et le. Les formules précédentes s'appliquent à toutes les approximations successives, quelle que soit la puissance de la force perturbatrice à laquelle on s'arrête; mais elles se simplifient quand on se borne à considérer les termes du premier ordre par rapport à cette force. En effet, puisque d'après sa définition, & doit être une quantité telle qu'en la substituant à la place de - dans la valeur de A, elle donne la valeur de cette fonction relative au mouvement troublé, en faisant abstraction des forces perturbatrices, on aura  $\zeta = \tau_1$  et par conséquent  $\frac{d\zeta}{dz} = 1$ . Quant à la constante β, n° 4, nous observerons qu'elle ne peut contenir la constante + quand on néglige les termes de l'ordre du carré des masses, puisque & n'est qu'une simple sonction des élémens elliptiques qui ne renferment pas cette quantité; on a donc dans la première approximation de = 0, et par conséquent

$$\frac{d\beta}{dt} = \frac{d \cdot l_{\xi}}{dt} - \frac{d \cdot l_{\xi}}{dt} \cdot \frac{d\zeta}{dt}.$$

Supposons qu'on désigne par l(e) la valeur de  $l_e$ , dans laquelle on surait substitué  $\zeta$  à la place de r, il est évident qu'on aura

$$\frac{d.l(e)}{dt} = \frac{d.le}{dt} - \frac{d.le}{d\zeta} \cdot \frac{d\zeta}{dt};$$

et par conséquent  $\frac{d\beta}{dt} = \frac{d \cdot l(e)}{dt}$ . Ainsi donc, dans la première approximation, on aura

$$\left(\frac{d\zeta}{d\tau}\right) = \tau, \quad \left(\frac{d\beta}{d\tau}\right) = 0,$$

et par suite

$$\frac{d^2\zeta}{drdt} = T, \quad \frac{ds}{dt} = \frac{d \cdot l(\zeta)}{dt} = S,$$

équations dans lesquelles on substituera pour T et S leurs valeurs pré-

Dans la seconde approximation et dans les suivantes, il faudre, dans les expressions de T et S, substituer pour  $\begin{pmatrix} d\xi \\ d\tau \end{pmatrix}$  et  $\begin{pmatrix} d\theta \\ d\tau \end{pmatrix}$  leurs valeurs résultantes des approximations inférieures. Or, la première approximation donners  $\xi$  et  $\theta$  exprimés en fonction de t et de  $\tau$ ; ces valeurs différentiées par rapport à  $\tau$ , donneront immédiatement les quantités  $\begin{pmatrix} d\xi \\ d\tau \end{pmatrix}$  et  $\begin{pmatrix} d\theta \\ d\tau \end{pmatrix}$ , telles qu'elles doivent être employées dans la seconde approximation. Cette nouvelle approximation fera connaître de la même manière les valeurs de ces deux quantités qui doivent être employées dans la troisième, et ainsi de suite.

Au moyen des valeurs précédentes de  $\frac{d\xi}{d\tau}$  et de  $\frac{d\theta}{dt}$ , l'équation (9), en l'intégrant, devient, relativement à la première approximation,

$$2l(\xi) = \frac{dR}{dt} \int \frac{dR}{dt} dt - \left(\frac{d\xi}{dt}\right); \quad (10)$$

on aura donc, par une simple différentiation, la valeur de I(g) larsque celle de  $\zeta$  sera déterminée, et en changeant ensuite  $\tau$  en t dans cette expression, on aura celle de I(r).

Quant à la constante introduite per l'intégration dans l'équation précédents, pour la déterminer observons que cette équation tient lieu de la suivante  $l(\xi) = \int Sdt$ ; or,  $l(\xi)$  est, par hypothèse, la variation de le calculé dans l'orbite elliptique, en y substituent  $\xi$  à la place de  $\tau$ . Si l'on ajoute donc au second membre de l'équation (10) la valeur de  $\xi$  relative au mouvement elliptique, en supposant que dans les formules qui s'y rapportent on ait changé  $\tau$  en  $\xi$ , le premier membre donners la valeur totale de  $\xi$  dans l'orbite troublée, sans l'introduction d'auçune autre constante.

Tout se réduit donc à déterminer la valeur de  $\zeta$ . Nous avons, par ce qui précède,  $\frac{d\zeta}{dt} = \int T dr$ , et nous avons vu que si après l'intégration on change r en  $t_1$  le second membre de cette équation doit se rédaire à zéro, ce qui détermine la constante comprise sous le signe f, laquelle

doit être une fonction de t. Par une seconde intégration, on aura

$$\zeta = \tau + \int dt \int T d\tau$$

* étant la constante introduîte par l'intégration. En effet, puisque  $\zeta$  est, d'apprès la signification de cette quantité, une fonction qui, substituée à la place de  $\tau$  dans la valeur elliptique de  $\lambda$ , donners la valeur de cette quantité dans l'hypothèse du mouvement troublé, on doit avoir  $\zeta = \tau$  quand on fait abstraction des forces perturbatrices.

9. Il ne s'agit donc, pour avoir la valeur de  $\zeta$ , que de développer l'expression de T, n,  $\eta$ , mais auparavant il sera bon de faire quelques observations, générales sur la forme de ce développement et sur la nature des différent termes qui en résulteront dans l'expression de  $\zeta$ . D'après la méthode ordinaire d'approximation, il faudra, dans les coefficiens qui multiplient  $\frac{dR}{d\nu}$  et  $r\frac{dR}{dr}$  dans l'expression de T, substituer d'abord à la place de r,  $\mu$ ,  $\zeta$  et  $\lambda$  leurs valeurs elliptiques développées en séries de l'anomalie moyenne, séries qui seront convergentes tant que les excentricités seront peu considérables, comme cela a lieu pour les planètes principales. On développera de la même manière les fonctions  $\frac{dR}{d\nu}$  et  $r\frac{dR}{dr}$ , et nous donnerons plus loin le moyen de déterminer les différens termes de ces séries, indépendamment de la grandeur des excentricités et des inclinaisons. En multipliant ensuite ces séries par les coefficiens qui s'y rapportent, développés comme nous l'avons indiqué, on obtiendra la valeur des Tréduite en série, dont la loi sera ordinairement facilé à saisir.

On doit observer que comme les différences  $\frac{dR}{d\nu}$ ,  $r\frac{dR}{dr}$  ne contiennent pas », l'intégration relative à cette quantité peut tonjours s'effectuer, dans toutes les approximations successives, soit avant soit après le développement de ces sonctions.

Digitized by Google

vraies, et des rayons vecteurs de la planète troublée et des planètes par, turbatrices; on pourra donc obtenir aisément les valeurs de plus en plus approchées de ces quantités, dont on a besoin dans la seconde approximation et dans les suivantes, lorsqu'on aura déterminé les valeurs de  $\zeta$  et de  $l_c$  résultantes des approximations précédentes. Les formules que nous donnerons plus loin feront connaître les valeurs des inclinaisons et des longitudes des nœuds relatives à la première puissance des forces perturbatrices, et qu'il faudra substituer dans  $\frac{dR}{dv}$  et  $r\frac{dR}{dr}$  horsqu'on s'occupera de la seconde approximation, et ainsi de suite dans les approximations successives. Quant au facteur  $\frac{an}{\mu \sqrt{1-e^2}}$  qui entre dans la valeur de T, on aura pour déterminer sa variation

$$d.l\frac{an}{\mu\sqrt{1-e^{\lambda}}} = \frac{andt}{\mu\sqrt{1-e^{\lambda}}} \cdot \frac{dR}{dv},$$

Tout ce que nous venons de dire relativement à T s'appliquerait évidemment à S; mais nous n'aurons point besoin, comme on l'a vu, d'effectuer le développement de cette quantité, l'équation (9) devant tenir lieu de la seconde des équations (7).

 $(\tau - t) \triangle \cos(i'n't - int + i's' - is) + (\tau - t) \triangle \sin(i'n't - int + i's' - is),$ où t' et i sont des nombres entiers, nt + s, n't + s' les longitudes moyennes de m et m',  $\Delta$  et B des coefficiens constans. En multipliant ces

^(*) On a vu, n° 3, que ces inégalités sont introduites par la considération du terme  $(t-\sigma)$  du dans l'expression de  $\frac{d\lambda}{dt}$ . Les termes qui croissent avec le terme t avaient disperu per la différentiation relative  $\lambda$   $\tau$ .

termes par de et en intégrant par parties, il en résultera dans & les softemes:

$$-\frac{A}{(i'n'-in)^2}\cos(i'n't-int+i's'-is) - \frac{B}{(i'n'-in)^2}\sin(i'n't-int+i's'-is),$$

$$+\frac{(\tau-t)A}{i'n'-in}\sin(i'n't-int+i's'-is) - \frac{(\tau-t)B}{i'n'-in}\cos(i'n't-int+i's'-is).$$

Les deux derniers termes se réduisent à zéro par la supposition de  $\tau = t$ ; les deux premiers donnent les inégalités provenant de la variation du moyen mouvement : ce sont les plus sensibles de la valeur de  $\zeta$  lorsqu'il existe un rapport de commensurabilité entre les moyens mouvemens des deux planètes m et m', à cause du très petit diviseur  $(i'n' - in)^*$  dont elles sont affectées.

L'intégrale / Tdr contiendra encore des termes de cette forme:

$$C\cos i(n\tau + \epsilon - \epsilon) + D\sin i(n\tau + \epsilon - \epsilon)$$
,

qui, étant multipliés par dt et intégrés, donneront dans ζ des termes où le tems t se trouvers hors des signes sinus et cosinus. On aura ainsi:

$$tC \cos i (n\tau + \epsilon - a) + tD \sin i (n\tau + \epsilon - a)$$
.

Si dans ces termes on change  $\tau$  en t, on aura les termes introduits par la partie séculaire de la variation des constantes arbitraires.

Il suit donc de ce qui précède que la valeur de  $\zeta$  se composera en général d'une suite de termes de la forme

$$a \sin(ig + i'g') + \beta \sin[\gamma + (i-1)g + i'g'] + \beta \sin[2\gamma + (i-2)g + i'g'] + \text{etc.}$$

$$+ i \sin[-\gamma + (i+1)g + i'g'] + \beta \sin[-2\gamma + (i+2)g + i'g'] + \text{etc.}$$

$$+ i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'g' + i'$$

g et g' représentant, pour abréger, les anomalies moyennes des deux planètes, et y étant ce que devieut g quand on y change t en r; c'est-à-dire

 $+i'(nr-nt)\sin(ig+i'g')$ ,

qu'on aura y = nr + : - u.

Nous avons désigné par z ce que devient ζ par cette substitution; en changeant donc τ en t dans la fonction précédente, on aura les termes correspondans de la valeur de z. On trouvera ainsi

$$s = {\binom{a+\beta+b+e\text{tc.}}{+i+\theta}} \sin(ig+i'g') + {\binom{a'+\beta'+b'+e\text{tc.}}{+i'+\theta'}} \cos(ig+i'g');$$

et par cette expression on seit oppussent ses seinem flanqueles flanqueles flanqueles des termes de la valeur de z dépendant d'un argument déterminés ao

Il existe entre les quantités a, B, J, etc., diverses équations de condition qui peuvent être très utiles pour le vérification du calcult de leurs valeurs numériques. Ainsi, par exemple, la quantité ¿ étant une fonction de r composés, relativement à r, comme s l'est par rapport à t, on aura dans le mouvement elliptique

$$\frac{\overline{d\xi}}{dr} = \frac{ds}{dt}, \quad \text{are in a regularity rank.}$$

pourvu qu'après la différentiation on change r en é dans le premier membre de cette équation. (Nous indiquerons désormais par un tiret — cette mutation.) Cette équation doit encore subsister dans l'orbite troublée. On aura donc, en différentiant et comparant les valeurs précédentes de  $\zeta$  et de z,

Il existerait entre les coefficiens des différens termes du rayon vecteur résultant de l'intégration de la formule /Sdi des équations semillables, aguis ces équations semillables par les quantités y et d'i parce que l'expression du rayon vecteur ne contient pas de termes semillables à ceux qui ont ces quantités pour facteurs dans l'expression de

On peut encore trouver un grand nombre de relations qui serviront à vérifier les calculs numériques; mais sous ne nons arrêterons pas davantage sur ce sujet : ce que nous avons dit suffira pour indigage la marche à

suivre dans l'intégration de l'équation  $\frac{d\zeta}{d\epsilon} = \int T dr$ , et par suite dans les détermination des perturbations de la variable x. Un peut éténdre les mêmes considérations à celle des perturbations du rayon vecteur, mais on les obtiendra plus facilement, comme avue l'avens-dit, au moyen de l'équation (10) quand la valeur de  $\zeta$  sera connue.

10. Après cette digression sur la forme générale de la fonction Tdr et sur son intégration, reprenons la valeur de T du n° 7 pour lui faire subir quelques transformations qui rendront son idéveloppement plus facile.

Digitized by Google

on des se les sesses de la prémière poissance des forces perturbatrices,

$$\frac{1}{r} \left\{ 2 \frac{k \cos(n - \lambda) - r}{r} + 2 \frac{1}{a(1 - c^2)} \left[ \cos((n - \lambda) - 1) \right] \right\} \frac{an}{\sqrt{1 - c^2}} \frac{dR}{dr}$$

$$\frac{1}{r} \left\{ 2 \frac{1}{r} \sin((n - \lambda) - \frac{an}{\sqrt{1 - c^2}} \right] \frac{dR}{dr}$$
(11)

Nous introduirons d'abord à la place de la fonction  $\frac{d\mathbf{R}}{dv}$  la différence  $\frac{d\mathbf{R}}{ds}$  de R prise par rapport à s. Si l'on observe que s n'est introduit dans la fonction perturbatrice qu'autant qu'il est contenu dans r et dans  $v_j$  on sura

$$\frac{d\mathbf{R}}{d\mathbf{t}} = \frac{d\mathbf{R}}{d\mathbf{v}} \frac{d\mathbf{v}}{d\mathbf{t}} + \frac{d\mathbf{R}}{d\mathbf{r}} \frac{d\mathbf{r}}{d\mathbf{t}};$$

d'où, en mettant pour  $\frac{dv}{dt}$  et  $\frac{dr}{dt}$  leurs valeurs, on tire

$$\frac{dR}{dv} = \frac{r}{a^4 \sqrt{1-q^4}} \frac{dR}{ds} = \frac{er\sin(v-s)}{a(t-e^4)} r \frac{dR}{dr}$$

Si l'on substitue cette valeur dans l'équation (11), elle devient

The property of 
$$\frac{1}{a^2(1-a^2)}$$
 and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}{a^2(1-a^2)}$  and  $\frac{1}$ 

Cette expression se réduit aisément à une forme plus simple. En effet, par l'équation de l'ellipse, on a

$$\frac{1}{r} = \frac{r}{a^2(1-e^2)^2} + \frac{re\cos(v-u)}{a^2(1-e^2)^2} + \frac{e\cos(v-u)}{a(1-e^3)}.$$

Si l'on substitue cette valeur dans le premier terme du coefficient de dans l'équation présédente, on trouve alors, sprès une légère

duction, ce facteur égal à

$$\frac{2 \operatorname{crsin}(v-\lambda)}{a^{2}(1-c^{2})^{\frac{1}{2}}} + \frac{\operatorname{resin}(v-o)}{a(1-c^{2})^{\frac{1}{2}}} - \frac{\operatorname{cesin}(\lambda-o)}{a(1-c^{2})^{\frac{1}{2}}} - 2 \operatorname{cresin}(\lambda-o)}{a^{2}(1-c^{2})^{\frac{1}{2}}} + 2 \operatorname{crsin}(v-o)$$

$$+ 2 \operatorname{crsin}(v-o)$$

$$= \frac{e^{rsin}(v-o)}{a^{2}(1-c^{2})^{\frac{1}{2}}};$$

Et en lui ajoutant la quantité suivante, qui est identiquement nulle,

$$\rightarrow 2 \frac{e^{re^{a} \sin (v - \lambda)}}{a^{a} (-e^{a})^{\frac{5}{2}}} + 2 \frac{e^{re^{a} \sin (v - \omega) \cos (\lambda - c\omega)}}{a^{a} (1 - e^{a})^{\frac{5}{2}}} - 2 \frac{e^{re^{a} \cos (v - \omega) \sin (\lambda - \omega)}}{a^{a} (1 - e^{a})^{\frac{5}{2}}},$$

ce facteur devient

$$\frac{2\frac{e^{r}\sin(v-\lambda)}{a^{2}(1-e^{2})^{\frac{3}{2}}}}{a^{2}(1-e^{2})^{\frac{3}{2}}} + \frac{re\sin(v-\omega)}{a(1-e^{2})^{\frac{3}{2}}} - 2\frac{e^{r}\sin(\lambda-\omega)}{a(1-e^{2})^{\frac{3}{2}}}$$

$$+2\frac{e^{r}\sin(v-\omega)}{a^{2}(1-e^{2})^{\frac{3}{2}}} + \frac{1+e\cos(\lambda-\omega)}{1-e^{2}} - 2\frac{e^{r}\sin(\lambda-\omega)}{a^{2}(1-e^{2})^{\frac{3}{2}}} + \frac{1+e\cos(v-\omega)}{1-e^{2}}$$

ou, en réduisant,

$$2\frac{e^{r\sin(\nu+\lambda)}}{a^{4}(1-e^{2})^{\frac{3}{2}}}+3\frac{re\sin(\nu+a^{2})}{a(1-e^{2})^{\frac{3}{2}}}-4\frac{e^{r\sin(\lambda-a)}}{a(1-a^{2})^{\frac{3}{2}}}.$$

On peut réduire également, dans la même équation, le facteur de  $\frac{dR}{dt}$  à une forme plus simple. En effet, g désignant, comme précédemment, l'anomalie moyenne, on a g=nt+s-a; et si l'ou différentie et conficient par rapport à g, en observant qu'on a

$$\frac{dv}{dg} = \frac{a^{2}\sqrt{1-e^{2}}}{e!} \quad \text{et} \quad \frac{dr}{dg} = \frac{ae \sin(v \to e)}{\sqrt{1+ae^{2}}}, \text{ at the other state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state$$

on obtient la fonction suivante

$$\frac{2}{r} \frac{\sin(v-\lambda)}{\sqrt{1-e^{\lambda}}} dg - 2 \frac{\sin(v-\lambda)}{a(1-e^{\lambda})^{\frac{1}{2}}} dg + 4 \frac{\exp(v-\lambda)\sin(v-\lambda)}{a(1-e^{\lambda})^{\frac{1}{2}}} ag + 4 \frac{\exp(v-\lambda)\sin(v-\lambda)\sin(v-\lambda)}{a(1-e^{\lambda})^{\frac{1}{2}}}$$

$$e^{\cos(v-\lambda)} = \exp(v-\lambda)\sin(v-\lambda)$$

$$-4 \frac{\arcsin(v-v)}{a!(1-v^2)^{\frac{3}{2}}} dg - 2 \frac{\arcsin(v-v)}{a(1-v^2)^{\frac{3}{2}}} dg + 2 \frac{e^{2} \cosh(v-v)\sin(v-v)}{a(1-v^2)^{\frac{3}{2}}} dg.$$

Si dans le premier terme de cette fonction en sabritue pour  $\frac{1}{r}$  an valeur précédente, et qu'on multiplie son second terme par la quantité

$$r = \frac{r}{a(1-e^2)} + \frac{re\cos(r-e)}{a(1-e^2)},$$

elle deviendra égals à

$$-4 \frac{e^{r \sin (v-\lambda)}}{a^{4} (a-e^{4})^{\frac{1}{2}}} dg + 4 \frac{e^{r e \sin (k-\omega)}}{a^{2} (a-e^{4})^{\frac{5}{2}}} dg - 4 \frac{e^{r e \sin (v-\omega)}}{a (a-e^{4})^{\frac{5}{2}}} dg + 2 \frac{e^{s \sin (k-\omega)}}{a (a-e^{4})^{\frac{5}{2}}} dg - 2 \frac{r e \sin (v-\omega)}{a (a-e^{4})^{\frac{5}{2}}} dg.$$

Si l'on traite cette fonction comme on a fait plus haut le coefficient de  $r\frac{dR}{dr}$ , elle se change dans la suivante t

$$-4 \frac{e^{r\sin(v-\lambda)}}{a^2(1-e^2)^2} dg + 6 \frac{e^{e\sin(\lambda-w)}}{a(1-e^2)^{\frac{3}{2}}} dg - 6 \frac{re\sin(v-w)}{a(1-e^2)^{\frac{3}{2}}} dg;$$

on aura donc ainsi

$$T = an \left[ 6 \int_{a}^{e} \frac{e \sin(\lambda - \omega)}{a \left(1 - e^{2}\right)^{\frac{1}{2}}} dg - 6 \int_{a}^{e} \frac{r \sin(\nu - \omega)}{a \left(1 - e^{2}\right)^{\frac{1}{2}}} dg - 4 \int_{a}^{e} \frac{e \sin(\nu - \lambda)}{a^{2}} dg \right] \frac{dR}{d\epsilon}$$

$$\int_{a}^{e} \frac{e \sin(\nu - \omega)}{a \left(1 - e^{2}\right)^{\frac{1}{2}}} - 4 \frac{e \sin(\lambda - \omega)}{a \left(1 - e^{2}\right)^{\frac{1}{2}}} - 2 \frac{e^{r \sin(\nu - \lambda)}}{a^{2} \left(1 - e^{2}\right)^{\frac{1}{2}}} \right] r \frac{dR}{dr}. \quad (13)$$

La constante qui doit compléter les intégrales qui entrent dans le premièr facteur doit être déterminée par la condition que ces intégrales se réduisent à  $\frac{\xi^2}{a^2(1-e^2)}$  lorsqu'on y change t en x, et en effet si l'on fait cette même substitution dans l'expression (12), cette valeur est celle que prend le coefficient de  $\frac{dR}{ds}$ .

On peut encore donner à la fonction T une autre forme qui rend son développement plus facile. Si l'on décompose les sinus qui entrent dans les derniers termes des coefficiens de  $\frac{dR}{d\epsilon}$  et r  $\frac{dR}{dr}$  de l'équation précédente, en sinus et son us des angles  $v - \omega$ , et  $\lambda - \omega$ , en observant que l'on a

$$\frac{d^{2} \frac{r^{2}}{a^{2}}}{dg} = \frac{2re\sin(\mu - a)}{a\sqrt{1 - a^{2}}}$$

the transfer of the second section of the second of

on trouve que la valeur totale de ce coefficient est égale à

const. 
$$-3\frac{r^2}{a^2(1-e^2)} - 2\frac{r^2 \xi \cos{(\lambda-e)}}{a^2 e(1-e^2)} + 2\frac{\xi \sin{(\lambda-e)}}{a(1-e^2)} \left[2\frac{r}{a}\cos{(e-e)} + 3e\right] dg_2^{a}$$
 (14)

et pour déterminer la constante, d'après ce qui a été dit numéro précédent, en faisant  $\gamma = n z + \epsilon - \sigma$ , on aura l'équation

const. 
$$-3\frac{\xi^2}{a^3(1-e^2)} - 2\frac{\xi^2 \cos(\lambda - e)}{a^3e(1-e^2)} + 2\frac{\xi \sin(\lambda - e)}{a(1-e^2)^{\frac{3}{2}}} \int \left[2\frac{\xi}{a}\cos(\lambda - e) + 3e\right] dy = \frac{\xi^2}{a^2(1-e^2)};$$

de là on tire

const. = 
$$4\frac{\xi^{1}}{a^{2}(1-e^{3})} + 2\frac{\xi^{3}\cos(\lambda-e)}{a^{3}e(1-e^{3})}$$
  
 $-2\frac{\xi\sin(\lambda-e)}{a(1-e^{3})^{\frac{3}{2}}}\int \left[2\frac{\xi}{a}\cos(\lambda-e) + 3e\right]d\gamma;$  (15)

et les deux intégrales qui entreront dans la fonction (14) après la substitution de cette valeur doivent être prises de manière qu'en supposant  $g = \gamma = 0$  elles prennent une valeur identique.

L'expression précédente de la constante peut se simplifier en mettant sous une autre some l'intégrale qu'elle renferme. En effet, si l'on désigne par l'anomalie excentrique correspondante à l = r, on aura

$$\begin{aligned} \xi \cos(\lambda - \omega) &= a \cos \theta - ae, \\ \xi \sin(\lambda - \omega) &= a \sqrt{1 - e^2 \sin \theta}, \\ dy &= d\theta (1 - e \cos \theta), \end{aligned}$$

et par suite

$$\int \left[2\frac{\xi}{a}\cos(\lambda-\theta)+3e\right]d\gamma = \int \left[2\cos\theta-e\cos2\theta-e^2\cos\theta\right]d\theta$$

$$= 2\sin\theta-e\sin\theta\cos\theta-e^2\sin\theta = \frac{\xi^2+a(1-e^2)\xi}{a^2\sqrt{1-e^2}}\sin(\lambda-\theta).$$
 (16)

On peut donc ainsi donner à l'équation (15) la forme suivante

const. = 
$$4 \frac{\xi^4}{a^2(1-e^2)} + 2 \frac{\xi^3 \cos(\lambda-\omega)}{a^3 e(1-e^2)} - 2 \frac{\xi^3 \sin^4(\lambda-\omega)}{a^3(1-e^2)^4} - 2 \frac{\xi^4 \sin^4(\lambda-\omega)}{a^4(1-e^4)}$$
,

ou bien, observant que l'en a sin'  $(\lambda - a) = 1 - \cos^2(\lambda - a)$  et

$$1 = \frac{\ell}{a(1-c^2)} + \frac{\ell^{c \cos(\lambda-\omega)}}{a(1-c^2)},$$

a près quelques réductions, on tronve

const. = 
$$2 \frac{\xi^3 \cos(\lambda - a)}{a^3 e} \left[ \frac{1 + e \cos(\lambda - a)}{1 - e^2} \right]^2 = 2 \frac{\xi \cos(\lambda - a)}{ae}$$
.

Si l'on substitue maintenant cette constante dans la valeur (14) du coefficient de  $\frac{d\mathbf{R}}{ds}$  dans l'équation (13), on aura

$$T = an \left\{ 2 \frac{e^{\cos(\lambda - \omega)}}{ae} - 3 \frac{r^{o}}{a^{2}(1 - e^{2})} - 2 \frac{r^{a}e^{\cos(\lambda - \omega)}}{a^{3}e(1 - e^{2})} + 2 \frac{e^{\sin(\lambda - \omega)}}{a(1 - e^{3})^{\frac{3}{2}}} \int \left[ 2 \frac{r}{a} \cos(\nu - \omega) + 3e \right] dg \right\} \frac{dR}{dt} + an \left[ 3 \frac{re\sin(\nu - \omega)}{a(1 - e^{3})^{\frac{3}{2}}} - 4 \frac{e^{e\sin(\lambda - \omega)}}{a(1 - e^{3})^{\frac{3}{2}}} + 2 \frac{e^{r\sin(\nu - \omega)\cos(\lambda - \omega)}}{a^{2}(1 - e^{3})^{\frac{3}{2}}} \right] - 2 \frac{e^{r\sin(\lambda - \omega)\cos(\nu - \omega)}}{a^{2}(1 - e^{3})^{\frac{3}{2}}} r \frac{dR}{dr}.$$

Comme l'intégrale (16) s'évanouit quand  $\gamma = 0$ , l'intégrale indiquée dans l'équation précédente, doit être prise de manière qu'elle s'évanouisse également quand on suppose g = 0.

Cette expression de T quoiqu'elle paraisse plus compliquée que l'expression (1 r') de la même quantité, a sur elle l'avantage d'exiger beaucoup moins de travail pour les calculs numériques, lorsqu'on veut déterminer à la fois les perturbations de deux ou d'un plus grand nombre de planètes soumises à leur action réciproque, parce que les quantités  $\frac{dR}{ds'}$ ,  $r'\frac{dR}{dr'}$ , etc., dont on a alors besoin, peuvent se déduire très simple-

ment des quantités  $\frac{d\mathbf{R}}{dt}$ ,  $r\frac{d\mathbf{R}}{dr}$ , relatives à la planète m qui sont déjà calculées.

En différentiant la valeur de  $\frac{r^2}{a^2}$  nous avons trouvé plus haut

$$\frac{d \cdot \frac{r^2}{a^2}}{dg} = 2 \frac{re \sin (v - a)}{a \sqrt{1 - c^2}};$$

on aurait de même

$$\frac{d \cdot \frac{r^a}{a^2}}{de} = -2 \frac{r}{a} \cos(v - v),$$

$$\frac{d \cdot \frac{\xi^2}{a^2}}{d\gamma} = 2 \frac{\xi e \sin(\lambda - v)}{a \sqrt{1 - \xi^2}},$$

$$\frac{d \cdot \frac{\xi^2}{a^2}}{de} = -2 \frac{\xi}{a} \cos(\lambda - v).$$

Au moyen de ces valeurs, l'équation (17) peut se changer en celle-ci :

$$T = \frac{an}{1 - e^{a}} \left\{ \frac{\frac{r^{2}}{a^{2}} - 1}{e} \left( \frac{d \cdot \frac{\xi^{a}}{a^{a}}}{de} \right) + e \left( \frac{d \cdot \frac{\xi^{a}}{a^{a}}}{de} \right) - 3 \frac{r^{a}}{a^{3}} - \frac{1}{e} \left( \frac{d \cdot \frac{\xi^{a}}{a^{a}}}{dy} \right) \int \left[ \left( \frac{d \cdot \frac{r^{a}}{a^{a}}}{de} \right) - 3e \right] dg \right\} \frac{dR}{d\epsilon}$$

$$+ \frac{an}{1 - e^{a}} \left[ \frac{3}{2} \left( \frac{d \cdot \frac{r^{a}}{a^{a}}}{dg} \right) - 2 \left( \frac{d \cdot \frac{\xi^{a}}{a^{a}}}{dy} \right) - \frac{1}{2e} \left( \frac{d \cdot \frac{r^{a}}{a^{a}}}{dg} \right) \left( \frac{d \cdot \frac{\xi^{a}}{a^{a}}}{de} \right) + \frac{1}{2e} \left( \frac{d \cdot \frac{\xi^{a}}{a^{a}}}{dy} \right) \left( \frac{d \cdot \frac{r^{a}}{a^{a}}}{de} \right) \right] r \frac{dR}{dr}.$$

$$+ \frac{1}{2e} \left( \frac{d \cdot \frac{\xi^{a}}{a^{a}}}{dy} \right) \left( \frac{d \cdot \frac{r^{a}}{a^{a}}}{de} \right) \left( \frac{d \cdot \frac{r^{a}}{a^{a}}}{de} \right) \right] r \frac{dR}{dr}.$$

C'est à cette transformation qu'il convient enfin de s'arrêter comme la plus propre à donner aisément les coefficiens de  $\frac{dR}{dt}$  et  $r\frac{dR}{dr}$  développés en séries très convergentes par rapport aux excentricités et aux inclinaisons, ce qui nous sera très utile dans les recherches suivantes.

11. Pour effectuer ce développement, soit

$$\frac{r^2}{a^2} = 1 + K^k \cos kg,$$

$$\frac{t^2}{a^2} = 1 + K^k \cos kg,$$

en représentant par  $K^k$  cos kg et  $K^k$  cos kg une suite de termes périodiques, les indices k et k pouvant prendre toutes les valeurs entières depuis k et k égaux à  $\infty$  jusqu'à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux à k et k égaux ègaux à k et k égaux ègaux à k et k égaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux ègaux

De ces équations, on tire

$$\begin{pmatrix}
d \cdot \frac{r^a}{a^b} \\
\frac{d}{dg}
\end{pmatrix} = -kK^a \sin kg,$$

$$\begin{pmatrix}
d \cdot \frac{r^a}{a^b} \\
\frac{d}{de}
\end{pmatrix} = \begin{pmatrix}
\frac{dK^b}{de} \\
\frac{d}{de}
\end{pmatrix} \cos kg,$$

$$\begin{pmatrix}
d \cdot \frac{\xi^a}{a^b} \\
\frac{d}{dy}
\end{pmatrix} = -\kappa K^a \sin \kappa y,$$
(19)

$$\begin{pmatrix} \frac{d \cdot f_{a}}{d c} \end{pmatrix} = \begin{pmatrix} \frac{d K^{a}}{d c} \end{pmatrix} \cos w_{f},$$

$$\int \left[ \left( \frac{d \cdot \frac{f^{a}}{d c}}{d c} \right) - 3e \right] dg = \left( \frac{d K^{a}}{k d d} \right) \sin kg + \left( \frac{d K^{o}}{d c} \right) g - 3eg,$$

la valeur zero étant exceptée de celles qu'on peut donner à k dans la derhière de ces équations parte que nous avons écrit séparément les termes qui résultent de sette supposition. Maît, par le développement connu du rayon vecteur, on a K° = \frac{3}{6}e^2, et par conséquent

$$\frac{d\mathbf{K}^{\circ}}{de} = 3e.$$

Les deux derniers termes de l'intégrale précédente se détruisent donc, et l'on a simplement

$$\int \left[ \left( \frac{d \cdot \frac{r^{*}}{a^{*}}}{de} \right) - 3e \right] dg = \frac{d\mathbf{K}^{*}}{kde} \sin kg, \quad (20)$$

k pouvant prendre toutes les valeurs entières positives et négatives, celle de k = 0 exceptée. Comme le ascond membre de cette équation est nul par la supposition de g = 0, la condition indiquée dans le numéro précédent se trouve rigoureusement remplie.

Maintenant, si dans Péquation (18):on substitue les valeurs qui résultent des équations (19) et (20), qu aura

$$T = \frac{an}{1 - e^{a}} \left\{ \left[ \frac{K^{k}}{e} \left( \frac{dK^{k}}{de} \right) - a \frac{K^{k}}{e} \left( \frac{dK^{k}}{kde} \right) \right] \cos \left( ay + kg \right) \right\}$$

$$+ e \left( \frac{dK^{k}}{de} \right) \cos ay - 3K^{k} \cos kg - 3 \right\} \frac{dR}{de}$$

$$+ \frac{an}{1 - e^{a}} \left\{ \frac{1}{2} \left[ k \frac{K^{k}}{e} \left( \frac{dK^{k}}{de} \right) - a \frac{K^{k}}{e} \left( \frac{dK^{k}}{de} \right) \right] \sin \left( ay + kg \right) \right\}$$

$$+ 2aK^{k} \sin ay - \frac{3}{2}kK^{k} \sin kg \right\} r \frac{dR}{de}.$$

On voit par cette expression de T, que les coefficiens d'un terme dans lesquels on aurait à la fois k=0 et k=0, résulteront uniquement de la première partie de chacun des coefficiens de  $\frac{dR}{dr}$  et de  $r\frac{dR}{dr}$ , tandis que les coefficiens des termes où l'on aurait séparément k = o et = = o, se composeront des différentes parties de ces mêmes facteurs.

Les cas où l'on suppose k = 0 et n = 0, simultanément ou séparément, méritent une attention particulière.

Si l'on suppose à la fois k = 0 et x = 0, le coefficient de  $\frac{d\mathbf{R}}{dt}$  devient égal à

$$\frac{\mathrm{K}^{\circ}}{e} \left( \frac{d\mathrm{K}^{\circ}}{de} \right) + e \frac{d\mathrm{K}^{\circ}}{de} - 3\mathrm{K}^{\circ} - 3;$$

et, comme, par ce qui précède, on a K° = 3 et, et par conséquent  $\frac{d\mathbf{K}^{\circ}}{de} = 3e$ , cette quantité se réduit à

$$-3(1-\epsilon^4)$$

- 3(1 - c4). Si l'on suppose simplement k=0, le oscilloient de  $\frac{dR}{dt}$  shvient : .

$$\left[\frac{\mathrm{K}^{\circ}}{c}\left(\frac{d\mathrm{K}^{*}}{dc}\right)+c\left(\frac{d\mathrm{K}^{z}}{dc}\right)\right]\cos z_{Y}-3\mathrm{K}^{\circ}-3;$$

et, en substituant pour Ko sa valeur

$$\frac{5}{2}e^{\frac{dK^2}{de}}\cos xy - 3\left(\frac{3}{2}e^a + 1\right).$$

Si l'on suppose maintenant = o, le même coefficient devient

$$\left[\frac{K^{\lambda}}{e}\left(\frac{dK^{\circ}}{de}\right) - 3K^{\lambda}\right] \cos kg + e\frac{dK^{\circ}}{de} - 3,$$

ou bien, en mettant pour  $\frac{d\mathbf{K}^{\circ}}{de}$  sa valeur, le coefficient de  $\cos kg$  se réduit à zéro, et la fonction précédente devient

c'est-à-dire que dans le cas on s=0, quel que soit k, le coefficient que nous considérons se réduit à une quantité constante.

On ferait des remarques analogues sur les valeurs du coefficient de  $r(\frac{dR}{dr})$  relatives aux diverses suppositions précédentes. Supposons donc, abstraction faite du cas où l'on a k=0 ou  $\kappa=0$ ,

aup then 
$$\mathbf{A}^{k}$$
,  $k = \frac{1}{1-e^{s}} \left[ \frac{\mathbf{K}^{k}}{e} \left( \frac{d\mathbf{K}^{k}}{de} \right) - \kappa \frac{\mathbf{K}^{k}}{e} \left( \frac{d\mathbf{K}^{k}}{kde} \right) \right]$ ,

$$B^{*,k} = \frac{1}{2(1-e^2)} \left[ k \frac{K^k}{e} \left( \frac{dK^k}{de} \right) - \kappa \frac{K^k}{e} \left( \frac{dK^k}{de} \right) \right];$$

et pour les cas particuliers où l'on a k = 0 et k = 0 simultanément ou séparément, soit

$$A^{0,0} = -3$$
,  $A^{\kappa,0} = \frac{5}{2} \frac{e}{1-e^3} \left(\frac{dK^{\kappa}}{de}\right)$ ,  $B^{\kappa,0} = \frac{1}{2} \frac{\kappa}{1-e^3} K^{\kappa}$ ,  $A^{0,k} = 0$ ,  $B^{0,k} = 0$ ;

on aura généralement

$$T = an A^{x,k} \cos(xy + kg) \frac{dR}{ds} + an B^{x,k} \sin(xy + kg) r \frac{dR}{dr},$$

où l'on pourra donner à k et x toutes les valeurs possibles, les valeurs de  $A^{x,k}$ ,  $B^{x,k}$  relatives au cas où l'on a k = 0 ou x = 0 étant déterminées par les équations précédentes.

12. Il s'agit maintenant d'intégrer par rapport à r la fonction  $\int T dr$ . Comme la quantité r n'est pas contenue dans  $\frac{dR}{d\epsilon}$  ou r  $\frac{dR}{dr}$ , cette intégration ne présente aucune difficulté. Et en supposant, pour abréger, généralement

$$C^{x,k} = \frac{1}{1 - e^x} \left[ \frac{\mathbf{K}^k}{e} \left( \frac{d\mathbf{K}^k}{ude} \right) - \frac{\mathbf{K}^k}{e} \left( \frac{d\mathbf{R}^k}{kde} \right) \right],$$

$$D^{x,k} = -\frac{1}{2} kC^{x,k},$$

et en particulier

$$C^{0,0} = -3, D^{0,0} = -\frac{n-d}{1-e^{a}}, C^{0,0} = \frac{5}{2} \frac{e}{1-e^{a}}, C^{0,0} = \frac{5}{2} \frac{e}{1-e^{a}} \left(\frac{dK^{a}}{kde}\right), C^{0,k} = -\frac{5}{2} \frac{e}{1-e^{a}} \left(\frac{dK^{k}}{kde}\right), C^{0,k} = -\frac{1}{2} kC^{0,k}; C^{0,k} = -\frac{1}{2} kC^{0,k};$$

on aura

$$\int T dr = aC^{n,k} \sin(\kappa \gamma + kg) \frac{dR}{ds} + aD^{n,k} \cos(\kappa \gamma + kg) T \frac{dR}{ds} + aC^{0,0} (n_{\overline{s}} - n_{\overline{s}}) \frac{dR}{ds}.$$
(31)

Quant à la constante introduite par l'intégration, elle doit être, d'après ce qui précède, une fonction de ! déterminée de manière que l'intégrale soit nulle lorsqu'en y change  $\tau$  en !; or, il est sisé de voir que le dernier terme de l'équation précédents qui correspond au cas où l'on a = o, représente cette constante et satisfait à cette condition. En effet, d'après la valeur de T dans l'article précédent, la partie constante de cette fonction est égale à

on aura donc, en n'ayant égard qu'à ce terme,

$$\int \mathrm{T} d\tau = an\tau \, \mathbf{A}^{0,0} \frac{d\mathbf{R}}{dt} + \mathrm{const.};$$

et en changeant - en s, on aura l'équation de condition

Si l'on suppose donc, comme nous le faisons,

$$\int \mathrm{T} dr = a C^{0,0} (nr - nr) \frac{dR}{dr},$$

on aura

$$C^{\circ,\circ} = A^{\circ,\circ}$$
.

13. Occupons-nous d'intégrer, par rapport au tems t, l'équation (21). Pour cela, il faut développer d'abord la valeur de la fonction R'et

de ses différences qui entrent dans le second membre. Soit généralement

$$R = m'(i, i', c)\cos(ig + i'g') + m'(i, i', s)\sin(ig + i'g'),$$

$$r\frac{dR}{dr} = m'[i, i', c]\cos(ig + i'g') + m'[i, i', s]\sin(ig + i'g'),$$

les quantités marquées d'un accent se rapportant à la planète perturbatrice. Nous supposerons de plas, pour fixes les idées, que i peut prendre toutes les valeurs positives ou négatives comprises entre— $\infty$  et  $+\infty$ , mais que i s'étend seulement de 0 à  $+\infty$ , œ, ce qui revient au même, de —  $\infty$  à 0, en sorte que i' est toujours précédé du signe —.

L'expression précédente de R, en observant que l'on a  $g = nt + \iota - \sigma_1$  et  $g' = n't + \iota' - \sigma'$ , donne

$$\frac{d\mathbf{R}}{dt} = -m't(i, i', c)\sin(i\mathbf{g} + i'\mathbf{g}') + m't(i, i', s)\cos(i\mathbf{g} + i'\mathbf{g}').$$

En substituent à la place de r  $\frac{d\mathbf{R}}{dr}$  et de  $\frac{d\mathbf{R}}{dt}$  leurs valeurs dans l'équation (21), on aura

$$\int T d\tau = \frac{am'}{\mu} \left\{ C^{a,k}(i-k) (i-k,i',s) + D^{a,k}[i-k,i',c] \right\} \cos(\kappa \gamma + ig + i'g')$$

$$+ \frac{am'}{\mu} \left\{ C^{a,k}(i-k) (i-k,i',s) + D^{a,k}[i-k,i',s] \right\} \sin(\kappa \gamma + ig + i'g')$$

$$+ \frac{am'}{\mu} C^{0,0} i(i,i',s) x \cos(ig + i'g')$$

$$+ \frac{am'}{\mu} C^{0,0} i(i,i',s) x \sin(ig + i'g'),$$
(22)

où, pour abréger, l'on suppose  $x = n\tau - nt$ .
Nous avons, par ce qui précède,

En multiplient par nels Féquation précédente, et en l'intégrant, on

$$n\zeta = n(1-c)\tau$$

$$+\frac{nt'}{\mu}\frac{4m}{\sin+i'\pi'}\{(i-k)(i-k,i',c)C^{*,k} + [i-k,i',c]D^{*,k}\}\sin(x\gamma + ig + i'g').$$

$$\frac{m'}{\mu} \frac{an}{in+i'n'} \{(i-k)(i-k,i',s)C^{a,k} + [i-k,i',s]D^{a,k}\} \cos(ay+ig+i'g') + \frac{am'}{\mu} \left(\frac{n}{in+i'n'}\right)^{2} i(i,i',s)C^{0,0} \sin(ig+i'g') + \frac{am'}{\mu} \left(\frac{n}{in+i'n'}\right)^{3} i(i,i',s)C^{0,0} \cos(ig+i'g') + \frac{am'}{\mu} \left(\frac{n}{in+i'n'}\right) i(i,i',s)C^{0,0} x \sin(ig+i'g') + \frac{am'}{\mu} \left(\frac{n}{in+i'n'}\right) i(i,i',s)C^{0,0} x \cos(ig+i'g') + \frac{am'}{\mu} \left(\frac{n}{in+i'n'}\right) i(i,i',s)C^{0,0} x \cos(ig+i'g');$$

no est la constante qui doit être ajoutée à cette équation; nous lui avons substitué la quantité n(1-c) : en voici la raison.

L'équation précédente cesse d'être exacte dans le cas où l'on a i = i' = 0. Il faut, pour déterminer la partie de la valeur de  $n\zeta$  relative à ce cas, recourir à l'équation (22). On voit alors que la supposition que l'on a à la fois i = 0, i' = 0 et x = 0 introduit dans la valeur de  $n\zeta$  un terme de cette forme:

## Knt.

Ge terme s'ajoutera au moyen mouvement dans l'expression de la longitude moyenne: si l'on veut donc que la longitude moyenne soit la même dans l'orbite elliptique, et dans l'orbite troublée, il faudra déterminer la constante c, de manière à faire disparaître ce terme. Ainsi, en supposant c = K, on aura

no = no + o(no - no) + une suite d'inégalités périodiques.

Sindans pette expression non change s and prof se changers on six, et Poul sons and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company and an entre de la company an entre de la company an entre de la company an entre de la company an entre de la company an entre de la company antendre de la

ns = ns 👍 des inégalités périodiques, e a e e e e e e

et l'on pourra substituer pour n la valeur de cette quantité, qui résulte des observations, en faisant abstraction des inégalités périodiques.

14. Les équations (22) et (23), lorsqu'on voudra en faire usage, exigerant deux sommations, l'une relative à k, et l'autre relative à z. En effet, pour obtenir le terme de la valeur de nz qui dépend de l'argument ig + i'g', il faudra calculer, dans l'expression de  $n\zeta$ , les termes dépendans de l'argument  $z\gamma + (i-z)g + i'g'$ , ou l'on peut donner à z toutes les valeurs entières positives et négatives, y compris zéro. Ainsi, par exemple, pour

avoir dans nz le terme qui dépend de l'argument 3g + 2g', il faudra commencer par déterminer dans n', les coefficients des termes dont les argumens sont

$$0\gamma + 3g + 2g'$$
,  $-\gamma + 4g + 2g'$ ,  $-2\gamma + 5g + 2g'$ , etc,  
 $\gamma + 2g + 2g'$ ,  $2\gamma + g + 2g'$ , etc.

La suite de tous ces termes formera la série relative à s, et le coefficient de chacun d'eux sera lui-même composé d'une série de termes dont la réunion formera ce que nous appelons la sommation relative à k. Ainsi, par exemple, le soefficient de  $\sin(-\gamma + 4g + 2g')$ , dans la valeur de  $n\zeta$ , sera la somme de tous les termes suivans:

$$\left\{ 4(4,2,c)C^{-1,0} + [4,2,c]D^{-1,0} \right\}$$

$$+ \left\{ 5(5,2,c)C^{-1,7} + [5,2,c]D^{-1,-1} \right\}$$

$$+ \left\{ 6(6,2,c)C^{-1,-2} + [6,2,c]D^{-1,-2} \right\}$$

$$+ \text{ etc.}$$

$$+ \left\{ 3(3,2,c)C^{-1,1} + [3,2,c]D^{-1,1} \right\}$$

$$+ \left\{ 2(2,2,c)C^{-1,2} + [2,2,c]D^{-1,2} \right\}$$

Ces quantités doivent être multipliées par  $\frac{m'an}{\mu(in+i'n')}$  et l'on formerait

de la même manière les coefficiens de tous les termes semblables de la valeur de  $n\zeta$ . Les troisième et quatrième termes de l'équation (23) se rapportent au cas où l'on a z = 0, et leurs coefficiens se déduiront immédiatement et sans aucun calcul de ceux du développement de la fonction R. Quant aux deux derniers termes de la même équation, ils disparaissent quand on substitue t à la place de  $\tau$ ; cependant il est bon de les conserver dans la valeur de  $n\zeta$ , parce qu'ils pénvent servir à la vérification des calculs, comme on l'a vu n° 9, et qu'ils sont utiles d'ailleurs dans la seconde approximation.

On peut ainsi se faire une idée de la suite d'opérations que l'on aura à effectuer pour déterminer, par la méthode précédente, toutes les inégalités d'une planète. Au reste, l'usage que l'on fera de cette méthode apprendra de lui-même au calculateur les nombreuses simplifications qu'elle peut recevoir, et nous renvoyons, sur ce point, au mémoire de M. Hansen.

15. Les inégalités du rayon vecteur peuvent se déduire immédiatement de la valeur de ζ, au moyen de l'équation (9). Cette équation se

que de la première puissance du fires perturbatrices. En effet, on a alors, n° 8,

$$\frac{d\zeta}{d\tau} = 1 \text{ et } \frac{\frac{d \cdot l_2}{d\tau}}{\frac{d\zeta}{d\tau}} = 0;$$

et si, pour abréger, on fait

$$\frac{an}{\mu V} \cdot \frac{dR}{1 - \sigma^2} \cdot \frac{dR}{dv} = \frac{dV}{dt},$$

l'équation (9) se change dans la suivante

$$2 \frac{d \cdot l(e)}{dt} = \frac{dV}{dt} \rightarrow \frac{dV}{dedt}.$$

En multipliant par de cette équation, et en l'intégrant, on aura

$$2l(g) = V - \frac{d(g)}{ds}. \quad (24)$$

Nous écrivons ici  $(\zeta)$  au lieu de  $\zeta$  pour indiquer que la constante en  $\tau$ , qui a été jointe à l'intégrale dans la valeur de  $\zeta$ , doit ici être ornige.

Si Pon différentie par rapport à r l'équation précédente, comme V ne contient pas  $\tau$ , on aura

$$\frac{2.d.l(t)}{dt} = -\frac{d^*(t)}{dt^2}.$$

En indiquant, comme dans ce qui précède, par un tiret placé sur une quantité, que dans cette quantité t a été changé en r, en sorte qu'on ait

$$\frac{d.l(e)}{d\tau} = \frac{d.l(r)}{dt},$$

il résultera de l'équation prétédente

$$\frac{d.l(r)}{dt} = -\frac{1}{2} \frac{\overline{d^2 \zeta}}{dt^2},$$

Si l'on multiplie par de cette équation et qu'on l'intègre, on aura :

$$l(r) = -\frac{1}{4} \int \frac{d^2\zeta}{dr^2} + \text{const.}$$

.5:10

¿¡Ouppourra' donc déterminen le rayen matteur au magnet de gette équation, mus être obligé d'effectuer le développement de la feaction V. Quant à la constante qu'elle renferme, pour la déterminer observous qu'en changeant r en t dans l'équation (24) en a

$$l(r) = \frac{1}{2} \nabla - \frac{1}{2} \frac{d(s)}{dt};$$
 (25)

et, d'après ce que nous avons dit nº 8, la seule constante qui doité être ajoutés à cette équation est la valeur du rayon vecteur elle-même calculée dans l'orbite elliptique, mais en substituant dans les formules & à la place de ».

En comparant les deux valeurs de l(r), on serva

$$-\frac{1}{2}\int \frac{d\vec{k}}{dr^2} + \text{const.} = \frac{1}{2}S = \frac{1}{2}\frac{d(z)}{dt};$$

mais is premier terme, dans chacan des deux membres de cette équation, ne renferme augune quantité constante; on sura donc, par conséquent,

 $const. = -\frac{1}{4} \frac{d(s)}{dt},$ 

en l'ayant égard qu'à la partié constante de la valeur de 44. Quant se l'argentie, elle résulte très simplement de le condition qu'en c'est impacée n° 12, que le moyen mouvement soit dans l'orbite elliptique, et dess l'orbite troublée, éclui qui est donné pur les observations.

"Si l'on substitue pour V se valeur dans l'équation (26), on aura-

$$\int_{v}^{\infty} \frac{andt}{\sqrt{1-e^2}} \cdot \frac{dt}{dv} = 2l(r) + \frac{d(z)}{dt}.$$

En développant la fonction  $\frac{d\mathbf{R}}{dv}$ , et en effectuant l'intégration indiquée, on aura ainsi une équation de condition qui servira à vérifier les inégalités de l(r) et de (z), calculées par les formules précédentes.

16. Considérons maintenant les inégalités du mouvement en latitude. Si l'on rapporte le mouvement de me su plan de son orbite primitive; qu'en désigne par « l'inclinaissen de montré mobile; et la longitude de son nœud; qu'on fasse

 $p = \tan \varphi \sin \theta$ ,  $q = \tan \varphi \cos \theta$ ,

on aura, Mécanique céleste, supplément auraité vol.,

(3 + 3) nu (2 andt diff (n' + ni)

dp = andt diff (n' + ni)

dq = andt dR

(n' + ni)

pour l'uneant d'où l'un compie le resce, pre en et gen ne les suites de p et de q étent (A) utentimente, on auraperties de la latitude e de me su derave de la latitude e de me su derave de la latitude e de me su derave de la latitude e pellement par l'éque

$$dq = \frac{andt}{\sqrt{1-c^2}} \left( \frac{dR}{\sin \gamma d\sigma} \right) + \frac{andt}{\sqrt{1-c^2}} \tan \frac{1}{2} \gamma \left( \frac{dR}{dv} \right).$$

Ces formules supposent que les longitudes sont commisse de la commune intersection des deux orbites nes tradice qu'en continue a la commune intersection des deux orbites nes tradices qu'en continue a de des fonctions de près la différentiation relative de variations de la comme une fongique des continues de la comme une fongique des continues de la comme une fongique des continues des différences de la relative de continue de différences de la relative de continue de la fonction de la comme de la comme de la fonction de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme de la comme

$$\frac{dR}{dy} = m'(i,i',c)' \cos(ig + i'g') + m'(i,i',j') \sin(ig + i'g')$$

$$\frac{dR}{\sin \gamma ds} = m'[i,i',c]' \cos(ig' + i'g') + m'D_i,i',s]' \sin(ig + i'g').$$

En observant qu'on a suppossi, d'ailleurs

Les constantes arbitraines qui doivent être jointes à ces intégrales sont nulles, puisque le plan des coordonnées étant celui de l'arbitra de  $m_2$  on a pour l'instant d'où l'on compte le tems, p = 0 et q = 0.

Les inégalités de p et de q étant ainsi déterminées, on para celles de la latitude s de m au-dessus de man orbite prinitive par l'équation

Dans les applications de ces formules aux planètes principales, on pourra généralement négliger les puissances de p et de q, supérieure l'hi première; ces quantités étant de l'ordre des forces perturbatrices et dans l'expression de la latitude, il suffira de substituer à la place de la longitude vrale », la longitude moyenne nt + relative au mou-

The Reprencies maintenant l'équation (18) et voyons comment se formeront les valeurs numériques des différentes quantités qu'elle renferme. Les quantités Da, a, Ca, à sont des fonctions connues des quantités que nous avons désignées par Ka, Ka, et de leurs différences de , de , de

cupons nous donc d'abord de ces quantités.

k et « pouvant prendre toutes les valeurs entières positives et négatives y compris zéro. K^k et Kⁿ sont des fonctions de l'excentricité de l'orhita de maqui pouvent toujours s'exprimes par des intégrales définies et se calculer par les quadratures. Mais lorsque les excentricités sont pen-

Digitized by Google

considérables, comme cela a lieu pour les planates principales, ou obtient leurs valeurs avec une précision suffisante en les réduisant en séries ordonnées par rapport aux puissances ascendantes de ces quantités. On a ainsi généralement

$$K^{(i)} = -\frac{\frac{2}{i^{2}} \left(\frac{ie}{2}\right)^{i}}{1,2.3...i} \left[1 - \frac{1}{i+1} \left(\frac{ie}{2}\right)^{2} + \frac{1}{1,2.(i+3)(i+2)} \left(\frac{ie}{2}\right)^{4} - \frac{1}{1,2.3(i+1)(i+2)(i+3)} \left(\frac{ie}{2}\right)^{2} \pm \text{etc.}\right].$$

La loi de cette série est évidente. Dans le cas particulier où i=0, on aura

(4) (基例を改集を)。 かいいおうりょう

En faisent successivement i=1, i=2, etc., dans la formule générale, on aura les valeurs de  $K^{(o)}$ ,  $K^{(i)}$ ,  $K^{(i)}$ , etc., et en les différentiant par rapport à  $\epsilon$  on en tirera celles de leurs différences  $\frac{dK^{(o)}}{de}$ ,  $\frac{dK^{(i)}}{de}$ , etc.;

il sera facile de calculer ensuite les valeurs correspondantes des  $\mathbb{D}^{n,k}$  et  $\mathbb{C}^{n,k}$ , dans lesquelles entrent ces quantités. Dans l'application des formes mules précédentes à la théorie de Jupiter et Saturne, il a suffi de porter l'exactitude jusqu'aux quantités dépendantes de la huitième puissance des excentricités, et de calculer par conséquent les quantités  $\mathbb{K}^{(n)}$ ;  $\mathbb{K}^{(n)}$ , etc., jusqu'à  $\mathbb{K}^{(n)}$ , inclusivement.

18. Il nous reste à montrer comment se calculeront, par la méthode des quadratures, les coefficiens des différens termes du développement de la fonction R et de ses différences partielles qui entrent dans les formules (22) et (23). Pour cela représentons en général par  $\mathcal F$  une fonction périodique des deux variables g et g' qui se développe en une série de cette forme

$$y = \mathbf{H}_{i,i'}\cos(ig + i'g') + \mathbf{H}'_{i,i'}\sin(ig + i'g'),$$

i et i étant deux nombres entiers qui peuvent s'étendre l'un et l'autre depuis —  $\infty$  jusqu'à +  $\infty$ .

On sait que pour déterminer les coefficiens  $H_{i,i'}$  et  $H'_{i'i'}$ , on aura les formules suivantes: (Connaissance des Tems 1836.)

$$\begin{split} H_{i,i'} &= \frac{1}{2\pi^{k}} \int_{0}^{2\pi} \int_{0}^{2\pi} y \cos{(ig + i'g')} \, dg \, dg', \\ H'_{i,i'} &= \frac{1}{2\pi^{k}} \int_{0}^{2\pi} \int_{0}^{2\pi} y \sin{(ig + i'g')} \, dg \, dg', \end{split}$$

et pour le cas particuliur où l'on a simultanément i zz o et l'az o, on aura

$$H_{o,o} = \frac{1}{(2\pi)^4} \int_{0}^{.2\pi} \int_{0}^{6\pi} \, y dg \, dg',$$

toutes les intégrales indiquées devant s'étendre depuis g et g' égaux à zéro, jusqu'à g et g' égaux à 2m.

Pour effectuer l'intégration des formules précédentes par la méthode des quadratures paraboliques, on considérera y comme l'ordonnée d'un paraboloïde dont g et g' sont les deux autres coordonnées, et l'on aura à déterminer la partie du solide comprise entre la surface et les plans des gg', et les plans menés par les deux extrémités parallèlement aux deux autres plans coordonnés. Pour cela on divisera l'intervalle compris entre g = 0 et g = 2x en n parties égales, et de même l'intervalle compris entre g'=0 et g'=2x en n' parties: il faudra que ces parties solent assez petites pour que les valeurs de y ne passent pas trop souvent du positif au négatif, ce qui altérarait l'exantitude des résultats, et que leur nombre cependant ne soit pas assez multiplié pour rendre les calculs impraticables par leur longueur. Dans l'application des formules prénédentes à la théorie de Jupiter et de Saturne, il a suffi de faire n mu de et n' mu fo. Nous nous arrêterens donc ici à ces deux suppositions.

Cela posé, si l'on fait

$$(i, i', c, c') = \frac{1}{2\pi^2} \int_0^{2\pi} \int_0^{2\pi} y \cos ig \cos ig' dg dg',$$

$$(i, i', c, s') = \frac{1}{2\pi^2} \int_0^{2\pi} \int_0^{2\pi} y \cos ig \sin ig' dg dg',$$

$$(i, i', s, c') = \frac{1}{2\pi^2} \int_0^{2\pi} \int_0^{2\pi} y \sin ig \cos ig' dg dg',$$

$$(i, i', s, s') = \frac{1}{2\pi^2} \int_0^{2\pi} \int_0^{2\pi} y \sin ig \sin ig' dg dg',$$

ces quatre intégrales doubles étant prises dans les mêmes limites que les précédentes.

On aura évidemment

$$H_{i,i'} = (i, i', c, c') - (i, i', s, s'),$$
  
 $H_{i,i'} = (i, i', s, c') + (i, i', c, s').$ 

On obtiendra donc immédiatement les valeurs des quantités  $\mathbf{H}_{i,i'}$  et  $\mathbf{H}'_{i,i'}$ ,

lorsqu'on connaîtra celles des quatre latégrales précédentes. Occupones nous donc de les déterminer.

Considérons d'abord la première. Ayant divisé comme nots l'among dit g en trente-deux et g' en seize parties égales, on commencera par calculer les 32 valeurs de y, qui répondent à g'= o et successivement  $g = 0, g = \frac{2\pi}{32} = 11^{\circ}15', g = 2\frac{2\pi}{32} = 22^{\circ}30', \text{ etc.}, \text{ jusqu'à i.e.}$ g=31  $\frac{2\pi}{20}=348^{\circ}45'$ . Nous désignerons respectivement ces valeurs de par Y,,o, Y,,o, etc., jusqu'à Y31,o. On supposera chisante 27 et l'on esiculera les valeurs respectives de 7 en dominant successivement à g les mêmes valeurs que pescidemmentapet al pendies gnera semblablement les valeurs resultante que (1,000 Kin . Xo. , , etc.) Here a suppose of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second o valeurs de y correspondantes à cette suppasition et a sus valeurs gungas sives de g, et ainsiede suite jusqu'à ce qu'on arrive à g profit de sives de g, et ainsiede suite jusqu'à ce qu'on arrive à g profit de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communication de la communi Quand ces calculs scront athetes our effectives must poing l'infigration relative à g, et les valeurs de praises déterminées servicont de han Pintégration qui doit suivre et qui est relative de gui la effet estange que g'étant constant et égal à i 25 dans la valeur de f, en detéloppant cette fonction par rapport à l'angle gion ait généralement

$$\mathbf{y}_{i'} = (i, c)_{i'} \cos i\mathbf{g} + (i, s)_{i'} \sin i\mathbf{g},$$

(i, c)i' et (i, s)i' désignant ainsi respectivement les coefficiens de cos if et de sin is dans ce développement; pour déterminer ces quantités on aura

$$(i,c)_{i'} = \frac{1}{\pi} \int_{0}^{2\pi} y_{i'} \cos igdg,$$

$$(i,s)_{i'} = \frac{1}{\pi} \int_{0}^{2\pi} y_{i'} \sin igdg.$$

Or, on peut regarder y comme l'ordonnée d'une courbe parabolique, dont l'abscisse est g, et d'après les formules commes et de qui précède, on aura, à très peu près,

$$\int y' \cos ig dg = \frac{2\pi}{n} \left[ Y_{0,i'} + Y_{1,i'} \cos i \frac{2\pi}{n} + Y_{1,i'} \cos 2i \frac{2\pi}{n} \dots + Y_{n-1,i'} \cos (n-1)i \frac{2\pi}{n} \right], \tag{26}$$

et Post auralt pour fre sin igig ; la même expression dans laquelle on changera sculement les cosinus en sinus.

Jefordenick done minnion was a first to the western and first the same of the same

$$\begin{aligned} &\{i,c\}_{i}' = \frac{1}{2\pi} \left[ Y_{\bullet,i}'\cos i(0) + Y_{i,i}'\cos i(1) + Y_{\bullet,i}'\cos i(2) ... + Y_{\bullet-i,i}'\cos i(31) \right], \\ &\{i,c\}_{i}' = \frac{1}{12\pi} \left[ Y_{\bullet,i}'\sin i(0) + Y_{\bullet,i}'\sin i(1) + Y_{\bullet,i}'\sin i(2) ... Y_{\bullet-i,i}'\sin i(31) \right], \end{aligned}$$

en représentant respectivement pour abréger par (o), (1), (2), etc., les quantités 0,  $\frac{2\pi}{32}$ ,  $2\frac{2\pi}{32}$ , etc. Dans ces formules i et i' penvent avoir toutes les valeurs entières possibles, positives ou négatives. En faisant donc successivement i'=0 et i=0, i'=0 et i'=1, on formera les expressions qui conviennent aux différentes quantités  $(0, c)_0$ ,  $(1, c)_0$ ,  $(i, s)_0$ , etc., et Pou pourra par sonséquent calculer ces quantités. Lorsque leurs valeurs seront toutes déterminées, on pourra regarder comme achevée l'intégration relative à i' d'il ne restera à effectuer que l'intégration relative à i'. Cette intégration peut se faire par les mêmes formules dans lesquelles on changera simplement  $Y_{i,i'}$  en  $(i, c)_{i'}$  ou  $(i, s)_{i'}$ , et où l'on substituera pour i et i' les indices convenables.

En effet, en considérant l'intégrale sir pos ig cos ig dgdg comme la somme de tous les petits parallélépipèdes dans lesquels on a décomposé le partien de solide comprise entre les limites données à g et g, il est gisé de voir qu'on aura

on aura donc, par ce qui précède,

Or, par la formule générale (26), on a

$$\int_{0}^{2\pi} (i, c)_{i'} \cos i' g' dg' = \frac{2\pi}{n'} \left[ (0, c)_{i'} \cos i' (0) + (1, c)_{i'} \cos i' \frac{2\pi}{n'} + (2, c)_{i'} \cos 2i' \frac{2\pi}{n'} + (15, c)_{i'} \cos 15, i' \frac{2\pi}{n'} \right];$$

on aura donc généralement,

$$n'(i,i',c,c') = (0,c)_{i'}\cos i'(0) + (1,c)_{i'}\cos i'(1) + (2,c)_{i'}\cos i'(2)...$$

$$+ (15,c)_{i'}\cos i'(15), \qquad (28)_{i'}$$

$$n'(i, i', s, s') = (0, s) \sin i'(0) + (1, c) \sin i'(1) + (2, c) \sin i'(2) \dots + (15, c) \sin i'(15),$$

en représentant respectivement dans ces deux formules par (0), (1); (2), etc., les quantités  $\frac{2\pi}{16}$ ,  $2\frac{2\pi}{16}$ ,  $3\frac{2\pi}{16}$ , etc., puisque nous avons supposé que relativement à Saturne, il suffissit de faire n'=16. Quant sur quantités è et i elles peuvent prendre toutes les valeurs entières possibles, positives ou négatives. Si l'en vent déterminer simplement a moyen des formules précédentes, le coefficient d'un terme du développement de R dépendant d'un argument donné, il suffire de substituer dans les formules (27) et (28) à la place de i et de i' leurs valeurs relatives à cet argument; mais lorsqu'on voudra déterminer au moyen des formules des  $n^{00}$  14 et 15 toutes les inégalités sensibles d'une planète, il faudra faire successivement i=0, i=1, i=2, etc., i'=0, i'=1, i'=2, etc., et former toutes les combinaisons qui résultent de ces diverses suppositions jusqu'à ce qu'on arrive à des inégalités dont les coefficiens soient inappréciables.

Dans l'application des formules précédentes, à la théorie de Jupiter et de Saturne, il a suffi de supposer i = 16 et i' = 7, et l'on n'a trouvé aucune inégalité sensible au-delà de ces deux suppositions. On a donc calculé au moyen des formules (27), les quantités suivantes

on a déterminé le système de valeurs semblables, qui se rapportent à la quantité (i,s);; on a eu ensuité par les formules (28) et (29) pour une releur quelconque de i:

$$16(i,0,c,c') = (i,c)_{\bullet} + (i,c)_{i} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + (i,c)_{1} + ($$

les quantités (o), (r), (2), etc., représentant respectivement...

o,  $\frac{2\pi}{16}$ ,  $\frac{2\pi}{16}$ , etc., c'est-à-dire, o°, 22°, 30′, 45°, etc. En faisant aux c'essivement dans ces formules i = 0, i = 1 jusqu'à i = 16, et en calculant par des formules analogues, les valeurs de (i, i', s, s'), (i, i', c, s') et (i, i', c, s'), on aura toutes les quantités nécessaires au développement de la fonction perturbatrice, dans la théorie de Jupiter et de Saturne.

it suffire d'y substituer à la place de y la valeur de la fonction perturbatrice, ou de celles de ses différences partielles que l'on voudra réduire en séries. Mais il faudra mettre auparavant ces valeurs sous la forme la plus simple pour les calcule numériques.

Nous avons supposé

$$B = m' \left( \frac{1}{\Delta} - \frac{xx' + yy' + zz'}{r^{3}} \right),$$

en faisant, pour abréger,

$$\Delta = \sqrt{(x'-x)^2 + (y'-y)^2 + (z'-z)^2}.$$

Si l'ou prend pour plan des ay celui qui passe par la commune intersection des orbites de m et de m', et qui est également incliné sur chacun de ces deux plans, en nommant I cette inclinaison et ce la longitude de la commune intersection des deux orbites, en faisant de plus, pour abréger,

$$u=v-\Pi,\ u'=v'-\Pi,$$

on aura

$$x = r \cos u$$
,  $y = r \sin u \cos \frac{1}{2} I$ ,  $z = r \sin u \sin \frac{1}{2} I$ ,

$$x' = r'\cos u'$$
,  $y' = r'\sin u'\cos \frac{1}{2}I$ ,  $z' = r'\sin u'\sin \frac{\pi}{2}I$ .

En substituant ces valeurs dans l'expression de a on trouve

$$\Delta^{a} = r'^{a} + r^{a} - 2r'r\cos^{a}\frac{1}{2}I\cos(u' - u) - 2r'r\sin^{a}\frac{1}{2}I\cos(u' + u).$$

Four simplifier les formules nous supposerons R partagé en deux parties et nous ferons

$$R_{i} = m' \frac{1}{\Delta}, \quad R_{ii} = -m' \frac{xx' + yy' + zz'}{r'^{3}};$$

en substituent pour A sa valeur et en différentient, on sura

int property of the transcurate of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cost of the cos = m' sin 1 m' nos(u'-u) - ry cos(u'-hu) m' sin t' ry sinusinu ล้า + _เร็ก**สูงเ**รื่องหนึ่งกับ สบอลเ**นส** Ces mêmes quantités, à l'exception de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence ran de la différence la théorie des deux planètes; Enfin, en substituant dans R, les valeurs de x, y, x, x, etc., on a'H wa - gannylanny : a M am a, andhrane a - w H'a aura R' = m'r (cos' +1 cos (sho-u)) + sho' + 1 sin (n' + 1) + sh et pour la munitaté analogue rélative à l'action de marque me (1770 e la R' - top 1 cos (u' - u) + sing ksin(u' + m) kso no ்ப்பு^{ப்ப}ாட்டாலும் நக்கும் <mark>வி வ</mark>ி et de ces expressions on tirera sans peine leurs différences relatives à r, r', I et n. On peut ainsi se faire une idée de la suite d'opérations que l'on aure à effectuer pour déterminer par la méthode précédente toutes les inégalités d'une plapète. Au reste, l'usage qu'on fera de cette méthodel apprendra de lui-même au calculateur les nombreuses simplifications qu'elle peut receroir, et nous reuneyans sur ce point su mémoire, de M. Hansen. 20. Nous terminerons cette analyse par la comparaison de quelques-un des résultats obtenus par cet astronome, à ceux qui résultent de la méthode ordinaire des séries, employée le plus souvent par les géomètres dans la théorie-des mouvemens planétaires.

En calculant par les quadratures le premier terme de la fonction par turbatrice R relative à l'action réciproque de Jupitér et de Saturne, e est

à-dire le terme non périodique de son développement, et en nommant m'F ce terme, M. Hansen a trouvé

$$a'F = 1.001007$$
,  $ad' \frac{dF}{dq} = 0.2238874$ ,  $a'' = (1.0)$ 

Les mêmes quantités calculées par le développement de R, en poussant la précision jusqu'aux quatrièmes puissances des excentricités et des inclinaisons inclusivement, sont

energy inverse. The property of all 
$$\frac{d\mathbf{F}}{da} = 0,2238867$$
. The property of the property of  $\frac{d\mathbf{F}}{da} = 0,2238867$ .

Can relaure and presque plentiques ....

Considérons en particulier les coefficiens des termes du développement de R relatifs à l'argument de la grande inégalité (*). En n'ayant égard qu'à ces termes, supposont v.

Par la méthode des quadratures, M. Hansen trouve pour l'année 1800

$$a'H = -0,000942079, a'H' = 0,0004023958,$$

$$a'^{a} \frac{dH}{dd} = 0.06849286$$

En calculant pour la mem époque ces quantités par le développement de la fonction perturbatrice (**), j'ai trouvé

shedring 
$$\frac{d\mathbf{H}_{i}}{d\mathbf{d}_{i}} = 0.0034486$$
, and  $\frac{d\mathbf{H}'}{d\mathbf{d}'} = -0.00307777$ .

Ces valeurs s'accordent sufficamment bien avec les précédentes si suntout

⁽¹⁾ Dans la note cités par M. Poissen dans son mémoire inséré dans la Connaissance des Tems pour 1836, j'avais comparé entre elles des quantités qui n'avaient pas la même signification dans la Mécanhque célesté et dans le mémoire de M. Habsen Lés conductions que j'ai tirées de cette comparaison sont douts dintives pur mémorale de seion la latitus estre extent.

si l'on observe que dans nos calculs nous avons employé pour les orbites de Jupiter et de Saturne les élémens de la Mécanique célesse, tandis que M. Hansen a adopté ceux qui résultent des tables de M. Bouvard.

Si l'on suppose maintenant

 $R = m'P \sin(5n't - 2nt + 5i' - 2s) + m'P' \cos(5n't - 2nt + 5i' - 2s),$ en comparant cette expression à la précédente, on trouvera

$$d'P = d'H' \sin (5e' - 2e) + d'H \cos (5e' - 2e),$$
  
 $d'P' = -d'H' \cos (5e' - 2e) + d'H \sin (5e' - 2e).$ 

En substituant dans ces expressions et dans leurs différences, pour H,  $H', \frac{dH}{da}$ , etc., leurs valeurs obtenues par les quadratures, on treu verx

$$a'P = -0,0000612864,$$
  $a'P' = 0,0010225843,$ 
 $a'^{a}\frac{dP}{da} = 0,00224621,$   $a'^{a}\frac{dP'}{da} = 0,00629075,$ 
 $a'^{a}\frac{dP}{da'} = -0,00116362,$   $a'^{a}\frac{dP'}{da'} = -0,00445304.$ 

La grande inégalité de Jupiter renferme le terme

$$\frac{6m'n^2a}{(5n'-2n)^4} \left\{ \begin{array}{l} a'P' \sin (5n't-2nt+5i'-2i) \\ -a'P \cos (5n't-2nt+5i'-2i). \end{array} \right\}$$

En supposant la masse de Saturne égale à 1/1278, d'après les valeurs rapportées dans la Mécanique céleste, tome III, on a

$$\log \frac{6m'n^2a}{(5n'_1-2n)^2\sin 1''}=6,0253350,$$

En réduisant en nombres la fonction précédente, d'après les valeurs de P et P' données plus haut, elle devient

$$1084'',012 \sin (5n't - 2nt + 5i' - 2i)$$
  
-  $64'',968 \cos (5n't - 2nt + 5i' - 2i)$ .

J'ai trouvé, par les formules ordinaires, cette inégalité égale à

$$1089'',855 \sin (5n't - 2nt + 5e' - 2i)$$
  
- 55'',204 cos (5n't - 2nt + 5e' - 2i).

Les différences sont dans les limites des quantités négligées dans le calcul. La grande inégalité de Jupiter contient encore la partie

$$\frac{2m'ne^2}{5n'-2n} \begin{cases} a'^2 \frac{dP'}{da} \sin (5n't - 2nt + 5s' - 2s) \\ -a'^2 \frac{dP}{da} \cos (5n't - 2nt + 5s' - 2s). \end{cases}$$

En la réduisant en nombres d'après les valeurs précédentes de  $d'^2 \frac{dP}{da}$ ,  $a'^2 \frac{dP'}{da'}$ , et observant qu'on a

$$\log \frac{2m'na^{6}}{(5n'-2n)\sin 1'} = 3,4140311,$$

cette fonction devient

- 
$$16',3205 \sin (5n't - 2nt + 5i' - 2i),$$
  
+  $5'',8275 \cos (5n't - 2nt + 5i' - 2i).$ 

Nous avons trouvé par le développement en série,

- 
$$56''$$
, 35386 sin  $(5n't - 2nt + 5i' - 2i)$ ,  
+  $6''$ , 05299 cos  $(5n't - 2nt + 5i' - 2i)$ ;

ce qui diffère peu de la valeur précédente.

La principale partie de la grande inégalité de Saturne est celle-ci :

$$\frac{15mn'^2}{(5n'-2n)^2} \left\{ \begin{array}{l} a'P'_i \sin (5n't-2nt+5i'-2i) \\ -a'P \cos (5n't-2nt+5i'-2i). \end{array} \right\}$$

En supposant la masse de Jupiter égale à 1053,924 de celle du So-leil, on a

$$\log \frac{15mn'^2}{(5n'-2n)^2 \sin^2 1} = 6,4193187.$$

En réduisent en nombres la fouction précédente au moyen des valeurs de s'P et s'P rapportées plus haut, on trouvers qu'il en résulte dans le mouvement de Saturne les inégalités suivantes:

$$-2685'',4543 \sin (5n't - 2nt + 5i' - 2i),$$

$$+ 160'',9470 \cos (5n't - 2nt + 5i' - 2i).$$

J'ai trouvé par les formules ordinaires (*)

$$-2678'',5574 \sin (5n't - 2nt + 5i' - 2i),$$
  
+  $156'',4072 \cos (5n't - 2nt + 5i' - 2i);$ 

ce qui diffère peu des valeurs précédentes.

Enfin, la grande inégalité de Saturne contient encore la partie sui-

^(*) Théorie du Système du Monde, tome III.

$$\frac{2mn'}{5n'-2n} \begin{cases} a'^{2} \frac{dP'}{da'} \sin (5n't-2nt+5i'-2i) \\ -a'^{2} \frac{dP}{da'} \cos (5n't-2nt+5i'-2i); \end{cases}$$

on a

$$\log \frac{2mn'}{(5n'-2n)\sin 1^{\circ}} = 4,0684515.$$

En réduisant en nombres la fonction précédente, d'après les valeurs de  $d'^a \frac{dP}{dd'}$  et de  $d'^a \frac{dP}{da}$  données plus haut, on aura

$$52^{\circ},1324 \sin (5n't - 2nt + 5i' - 2i),$$
  
-  $13^{\circ},6226 \cos (5n't - 2nt + 5i' - 2i).$ 

l'ai trouvé pour la valeur de cette même inégalité

49',39039 sin 
$$(5n't - 2nt + 5t' - 2t)$$
,

- 13',49618 cos  $(5n't - 2nt + 5t' - 2t)$ .

Il réquite de la compansion précédente que la méthode de départique loppement, en série de la fonction perturbatrice dans la théorie des appropriet roublés des planètes pa toute la précision dépitable, et que les inégalités planétaires calculées de cette manière proprent suffre parétaires calculées de cette manière proprent suffre parétaires calculées de cette manière proprent suffre parétaires de l'Astronomie.

Cette vérification était nécessaire apanes que les résultes séssiés estécnes les séries que lque lque qu'on peuses les approximations des sessites les séries que lque deute dans les espaits de muit descrété à désires proper par établir, immédiatement une sompéraison entre tentes les inégalités de la théorie de Jupiter et de Saturnes celculées pan Laplace et selles qu'a déterminées M. Hansen. Malhaurementant le choix des pouvelles veriables qu'il a substituées à celles qu'ont adéptées généralement les géopràtres et les astronomes, randrait sette vérification, très difficient chiques à des calous longs et pénilles.

¡On doit regretter que M. Hanson mait pas trouvé le moyen de défluire des résultats qu'il a obtenus les valeurs des variables endinaires, c'est-à-dire de la longitude, du region vecteur et de la latitude dans l'orbite troublée : c'est alors que son travail, un mérite réel qu'on ne peut lui refuser, aurait joint celui de l'utilité.

## NOTE

## Relative à l'attraction d'un ellipsoïde hétérogène;

PAR M. POISSON.

(Luc à l'Académie des Sciences, le 24 novembre 1834.)

Dans l'une des dernières séances de l'Académie, on a donné lecture d'une lettre de M. Jacobi, contenant l'annonce de deux résultats curieux, auxquels ce savant géomètre est récemment parvenu. L'un de ces résultats est relatif à la figure permanente d'un fluide homogène, tournant autour d'in azofixe, qui pout être un ellipseide à trois axes inégaux, ce qu'on Mavait point encore remarque. L'autre se rapporte au calcul de l'attrac-Hen'd'un ellipsoide hétérogène, dont les composantes penvent s'expri-Hier? dans certains ous, sous forme fine par des arcs de cercle ou des logarithmes, et sans le secours des fonctions elliptiques. Le premier de ces Udus résultats est moils à vérifier par les formules de la Mécanique réflèsie : mais il n'en est pas de même à l'égard de la seconde pro-Bostion : en moven des anciennes formules, étendues au cas d'un él-Mileste competé de constru de diverses densités, il servit difficile ede reconnective dans quels cas cos formales sont integrables sons forme Milit; et, en effet, M. Jacobi annouce que les intégrations qu'il vient d'eldictament autuchent hale nouvelles recherches qu'il à entreprises sur cette imatière. En attendunt que l'auteur ait publié sen analyse, je crois pouvoir observer que ces mêmes intégrations sont une conséquence qui se déduit hisiment des formules de mon mémoire sur l'Attraction d'un efficacide, imprime dans le XIII volume de l'Académie des Sciences, et dont fail distribute, il y a quelques mois, des exemplaires tirés à part." ... Sie l'on applique ces dormules à un allipsoide compesé de cottelles qui ont toutes leurs trois anes: suivant les mêmes directions et dans les mémies rapports de grandeur, et si l'on suppose que la densité de ce corps soit égale dans toute l'étendue de chacune de ces couches semblables, il en résulte que l'attraction qu'il exerce sur un point extérieur ou intérieur, se détermine par des intégrales simples, comme dans le cas d'un ellipsoide homogène. De plus, lorsque la densité varie d'une couche à une autre suivant une fonction rationnelle du carré de l'un des axes, multipliée ou divisée par la longueur de cette droite, il suffit de jeter les yeux sur ces intégrales pour voir qu'elles peuvent s'obtenir sous forme finie par les règles ordinaires. J'ai pris pour exemple le cas qui a été spécialement indiqué par M. Jacobi, où la densité varie en raison inverse de la longueur de l'un des axes, ce qui la rend infinie au centre, et n'empêche pas, néanmoins, que les composantes de l'attraction de l'ellipsoïde entier sur un point quelconque, ne soient des quantités finies. Ce cas, le plus simple pour le calcul, présente aussi cette circonstance remarquable, que l'attraction sur un point intérieur est indépendante de sa distance au centre de l'ellipsoïde, et ne varie qu'avec la direction de son rayon vecteur, en sorte que sur un rayon donné elle est la même, en grandeur et en direction, à la surtace et aussi près que l'on veut du centre de ce corps.

## 1. Représentons par

$$x^a + my^a + nz^a == k^a, \qquad (1)$$

l'équation de la surface de l'ellipsoïde donné; x, y, z, étant les coordonnées courantes, rapportées à ses trois axes de figure; k, m, n, des quantités positives; et k,  $\frac{k}{\sqrt{n}}$ ,  $\frac{k}{\sqrt{n}}$ , les longueurs des demi-axes.

Soient a, b, c, les coordonnées du point attiré, rapportées aux mêmes axes que x, y, s. Soient aussi X, Y, Z, les composantes suivant ces trois coordonnées, de l'attraction exercée par l'ellipsoïde sur le point donné. Désignons par  $\nu$  une quantité positive, déterminée par l'équation

$$\frac{a^{a}}{1+v} + \frac{mb^{a}}{1+mv} + \frac{nc^{a}}{1+nv} = k^{a}, \quad (2)$$

qui a toujours une racine réelle et positive, et n'en a qu'une soule, comme on le démontre aisément. Supposons d'abord l'ellipsoide homogène, et prenons sa densité pour unité. Le point attiré étant situé en de-hors de l'ellipsoide, en aura, d'après les formules du mémoire cité plus haut [équations (e') du n° 20],

$$X = 2\pi a \int_{\nu}^{\infty} \frac{du}{(1+u)\sqrt{\overline{U}}},$$

$$Y = 2\pi mb \int_{\nu}^{\infty} \frac{du}{(1+mu)\sqrt{\overline{U}}},$$

$$Z = 2\pi nc \int_{\nu}^{\infty} \frac{du}{(1+nu)\sqrt{\overline{U}}},$$
(3)

où l'on a fait, pour abréger,

$$(1 + u) (1 + mu) (1 + mu) = U,$$

et représenté, à l'ordinaire, par  $\pi$  le rapport de la circonférence au diamètre.

2. Je différentie ces formules par rapport à k, en y regardant a, b, c, m, n, comme des constantes; les intégrales ne dépendant de k qu'à raison de leur première limite v, on aura

$$dX = -\frac{2\pi a \frac{dv}{dk} dk}{(1+v)\sqrt{\overline{V}}},$$

$$dY = -\frac{2\pi mb}{(1+mv)\sqrt{\overline{V}}},$$

$$dZ = -\frac{2\pi nc}{dk} \frac{dv}{dk} dk$$

$$(1+mv)\sqrt{\overline{V}},$$

V étant ce que devient U quand on y met v au lieu de u, de sorte qu'on ait

 $V = (1 + \nu) (1 + m\nu) (1 + n\nu).$ 

Ges differentielles dX, dY, dZ, seront les composantes de l'attraction exercée sur le point donné, par une couche infiniment mince, comprise entre deux surfaces elliptiques semblables, dont l'épaisseur est dk aux extrémités des deux demi-axes k. Si l'on multiplie leur valeur par une quantité quelconque  $\ell$ , elles exprimeront les composantes de cette attraction dans le cas où la densité de cette couche homogène, au lieu d'être prise pour unité, serait représentée par  $\ell$ ; par conséquent, en preuant pour  $\ell$  une fonction donnée de k, et intégrant ensuite par rapport à k, lepuis une valeur donnée k = k' jusqu'à une valeur aussi donnée k = k, ious aurons les composantes X, Y, Z, de l'attraction d'une portion de

l'ellipsoide, contenant un composée de couches s

bles, et terminée per deux surfaces dont les demi-axes serent k,, 1 400 pour la surface intérieure, et.k., =, pour la sur extérieure. che fron wiit que deus le cas de l'homogénéité, ou de la densité e constante, chacate de ces compountes est proportionnelle à la coordonnée du public attiné anjunt laquelle elle agit.

Quand le point attiré aux situé dans l'intérieur de l'ellipsoide, et fera apartie d'aux sessait déterminée par l'équation (6). l'attraction de toutes les couches extérieures sur ce point sera, comme on sait, égale à séro, et l'attraction qu'il éprouvera se réduira à celle les véuches intérieures; d'est l'en couçtet que, dans ce cas, les consposantes de cette force seront encore exprimées par les formules (5), dans les quelles on fera *, = \infty, et pur les formules (7) lorsqu'il n'y aura pas de vide dans l'intérieur.

3. Dans chaque exemple, l'expression de para donnée en function de k; on y mettra pour k sa valeur tirée de l'équation (2); il en ministeré une valeur de p en fonction de v; et après l'ampir substituée dans les formules (5), il ne s'agira plus quivide réduite, s'il est passible, les intégrales qu'elles renferment, aux fountions elliptiques, aux arcs de cercles et aux logarithmes, ou bien si cette-méduction est impossible, il ne restera plus qu'à calculer les valeurs approchées de ces intégrales, par la méthode des quadratures, quand les valeurs numériques de a, b, c, m, n, seront données. Or, cette réduction serve possible toutes les fois que p sera une fonction rationnelle de k.

En effet, en pourra alors mettre l'expression donnée de paous la forme :

Tet Q étant des fonctions rationnelles de k2. D'ailleurs, la valeur de k tigrée de l'équation (2) peut aussi être représentée par

$$k = \frac{\sqrt{e^4 + 4f^4 + 4fg^4}}{\sqrt{\nabla}},$$

en faigent , nour absorer ;

$$a^{a_1} + mb^{a_2} + mc^{a_3} = c^{a_3},$$
 $(m+n)a^{a_1} + (1+n)mb^{a_2} + (1+m)nc^{a_3} = f^{a_3},$ 
 $mn(a^{a_1} + b^{a_2} + c^{a_3}) = g^{a_3}.$ 

En la mbetitionet dans la valeur de au et collegei dans les sormules (6). checune des intégrales qu'elle renferme prendre la forme y prent pour le principal de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de la company de

P'et Q'étant des fonctions rationnelles de v qui dépendrout respective ment de P et Q. Or, la première de ces intégrales est toujours réducible aux fonctions elliptiques, et la seconde peut toujours s'obtenir sous forme finie, sans le secours de ces fonctions.

Il résulte de la que le cas le plus simple n'est par celui de l'homorénéité, qui aurait lieu si Q était zéro et P une constante; mais, au contraire, le cas où P est zéro et Q une quantité constante, de sorte que la densité des couches de l'ellipsoide varie en raison auverse de la grandeur de l'un de leurs axes.

4. Considérons en particulier ce cas le plus simple; et faisons, en conséquence, /= 1:

$$y=\frac{\lambda}{k}$$
;

h étant une constante donnée. Les formules (5) deviendront

$$X = 2\pi ah \int_{v'}^{v} \frac{dv}{(i+v)\sqrt{e^{2}+vf^{2}+v^{2}g^{2}}}$$

$$Y = 2\pi mbh \int_{v'}^{v} \frac{dv}{(i+mv)\sqrt{e^{2}+vf^{2}+v^{2}g^{2}}},$$

$$Z = 2\pi nch \int_{v'}^{v} \frac{dv}{(i+nv)\sqrt{e^{2}+vf^{2}+v^{2}g^{2}}},$$

$$(3)^{11} = 2\pi nch \int_{v'}^{v} \frac{dv}{(i+nv)\sqrt{e^{2}+vf^{2}+v^{2}g^{2}}},$$

per conséquent, si l'on désigne per p une constante quelconque, et que l'on fasse

$$q = \int_{(1+P^{\nu})\sqrt{e^2 + vf^2 + v^2g^2}}^{d\nu},$$

il suffira de déterminer cette intégrale indéfinie : en passant mente l'intégrale définie, prise depuis v = v' jusqu'à  $v = v_i$ , et faisant successivement p = 1, = m, = n, dans le résultat, on aura les valeurs des intégrales contenues dans ces expressions de X, Y, Z.

Pour obtenir la valeur de q, je décompose la quantité comprise sous le radical en deux facteurs, et je suppose que l'on ait

$$e^{a} + vf^{a} + v^{a}g^{a} = g^{a}(v + a) (v + 6);$$

prenant pour l'est rélaient user saire le plus petit ou le plus grandes trois demi-axes de l'ellipsoide, de sorte que les différences 1—m et 1—n soient toutes deux mégatives ou toutes deux pésitives, et que leur produit soit toujours positif. En effet, pour la réalité de « et C, il est nécessaire et, il enfit que l'en produit toujours positif. au moyen de quoi la quantité q devient

$$q = \frac{2}{g} \int \frac{dx}{(ps-1)x^2 - (p\ell-1)}.$$

Si donc les ideux quantités ps — 1 et p6 — 1 sont de même signe, on aura

$$q = \frac{1}{g\sqrt{(p_{a}-1)(p_{a}^{a}-1)}} \log \frac{x\sqrt{p_{a}-1}-\sqrt{p_{a}^{a}-1}}{x\sqrt{p_{a}-1}+\sqrt{p_{a}^{a}-1}} + C;$$

et si elles sont de signes différens, on prendra

$$q = \frac{2}{s\sqrt{(p-1)(p-1)}} \operatorname{arc}(\operatorname{tang} = x\sqrt{\frac{pa-1}{1-pc}}) + C;$$

C étant, dans les deux cas, la constante arbitraire. En remettant pour x sa valeur, la première de ces expressions devient

$$q = \frac{1}{g\sqrt{(pa-1)(pb-1)!}} + \frac{\sqrt{(v+b)(pa-1)}-\sqrt{(v+a)(pb-1)}}{\sqrt{(v+b)(pa-1)}+\sqrt{(v+a)(pb-1)}} + C,$$

et la seconde prend la forme :

$$q = \frac{1}{g\sqrt{(pa-1)(n-pb)}} + C.$$

Si, par exemple, le point attiré est situé sur la direction de l'axe dont la demi-longueur est k, on sura

$$b = 0$$
,  $c = 0$ ,  $c = a^2$ ,  $f' = (m + n)a^3$ ,  $g' = mna^3$ ;

le trinome e1 + vf + v2ga deviendra a1 (1 + mv) (1 + nv); en sorte qu'il se décomposera en deux facteurs réels, sans qu'on art besoin de supposen que k' soit le plus petit ou le plus grand des trois de axes: il sera l'un on l'autre, on le demir-axe moyen, selon les valeurs que l'on attribuera à m et m. On fera

dans les expressions de q. La première aura lieu quand les quantilés # et n sevent tentes deux plus petites ou toptes deux plus grandes que l'unité, et elle deviendre

$$q = \frac{1}{a\sqrt{(1-m)}} \log \frac{\sqrt{(1+mv)(1-m)} - \sqrt{(1+mv)(1-m)}}{\sqrt{(1+mv)(1-m)} + \sqrt{(1+mv)(1-m)}} + C$$

On devra employer la seconde, savoir:

$$q = \frac{2}{u\sqrt{(i-m)(n-1)}} \arctan \left[ \tan g = \sqrt{\frac{(i+n\nu)(i-m)}{(i+m\nu)(m-1)}} + C_{i} \right]$$

lorsque l'une de ces quantités m et n sera plus petite et l'autre plus grande que l'unité ...

5. Quoique, dans cet exemple, la densité soit infinie au centre de l'ellipsoider les valeum de X. X. Z. que l'ou abtient en massant ent intégrales définies, sont néanmoins des quantités, finies, Mais si le noist attiré est situé dans l'intérieur de ce corps hétérogène, ces valeurs de meure contentes suivant chaque direction a depuis le centre juqu'à la surface. C'est effectivement ce que l'on peut voir sans même effectuer les intégrations; car, dans ce cas, les limites des littéllates sont v'=0 et  $v_r=\infty$  (9° 41; 40 ki l'ort désigne par r le rayon vecteur du point attiré, et par d, b, c', les cosinus des angles que fait sa direction avec les axes des coordonnées, de sorte qu'on aix est ne li

en désignant par e, f', g', des quantités indépendantes de r; par consequent, ce rayon disparaitra des formules (8), qui ne varieront plus, qu'avec sa direction.

En Lindie Successive successive states and one excession documents and appreciate do

pour l'attraction exercée sur un point quelconque du plus grand ou du plus petit axe de l'ellipsoide, et

pour sa valeur relative à un point quelconque de l'axe moyen.

Dans le bas d'un ellipsoide de révolution, on a  $n = m_j$  et, pour tous les points de l'une de ligere ; la gramière paleur de X se réduit à

$$\mathbf{X} = \frac{2\pi h \cos \beta \sin \beta \cos \beta \cos \beta \cos \beta \cos \beta}{m-1} \log m.$$

La seconde valeur, qui répondra à un point quelconque de l'équateur, deviendra d'abord

such some as  $\frac{\sqrt{1-m}\sqrt{\frac{m}{m}}}{\sqrt{1-m}\sqrt{\frac{m}{m}}}$  arc  $\left(\tan \frac{m}{m} + \frac{m}{m} + \frac{m}{m}\right)^{m}$  and  $\frac{m}{m}$  arc  $\frac{m}{m}$ 

Male, ten designant pair y une quantité réelle our insegnation entité par le principal de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la constant de la con

$$\operatorname{arc}\left(\operatorname{tang} = \frac{1-m}{1+m}\sqrt{-1}\right) = \frac{1}{\sqrt{-1}}\log\sqrt{m};$$

au moyen de quoi la seconde expression de X conncidera avec la première, qui conviendira, par consequent, à tous les points de l'axe et de l'équateur.

Epfin, dans le cas de la sphere, on aura m=1, et X=24h pour tous les points intérieurs. En faisant n= m= Y dans les formules (6);

et, supposent, tonjours les sphère entière, en trouve, viere pour le résul-

, by in run to wat in san a rout mother

d'après la loi des densités que l'on a supposée, si l'on représente par e la masse de la sphère dont le rayon est k', on aura aussi

$$\mu = 4\pi \int_{0}^{R} \frac{dx}{x^{2}} dx = 2\pi h k^{2} + \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}$$

l'attraction sur un point extérieur sera donc de qui est effective-

En désignant par r' la distance d'un point intérieur au centre de la sphère, et par  $\mu'$  la masse de la sphère concentrique dont la surface passe par ce point, on peut encore exprimer, quelle que soit cette loi, par  $\frac{\mu'}{r'^2}$  l'attraction sur ce point; valeur qui devient aussi  $2\pi h$  dans le cas particulier que nous considérons.

#### NOTE

Sur la détermination du prochain retour de la comète de 1759;

PAR M. G. DE PONTÉCOULANT.

Pai donné, dans la Connaissance des Tems pour 1833, les résultats des calculs que j'ai faits pour fixer l'époque du prochain retour à son périhélie de la comète de 1759, et les élémens de son orbite à cet instant. L'approche de cette époque et le désir de la déterminer avec le plus de précision possible, m'a engagé à revoir de nouveau ces calculs, et à y introduire quelques corrections dont voici les motifs: re la masse que j'avais employée pour Jupiter dans mes recherches est celle qui résulte

des équatitura de condition des tables de Ma Benvirale les calquis des inére galifes des petites planètes d'accord aves les neuvelles cherrations des élongations des satellites faites par M. Airy, ont montré que gette valeur avait besoin de correction, et la nouvelle masse surpasse de goin à peu près celle que les géomètres avaient adoptée depuis Newton, qui l'avait déduite des observations de Pound. Il a fallu corriger, par conséquent, les variations des disputas elliptiques de l'orbité de la comète, résultantes de l'action de Jupiter; et fon verra que ces corrections ne pouvaient être: mégligées, puisqu'elles altèrent de plus de deux jours la durée de la période actuelle de la comète. 2º. Fai remarqué ensuite que je n'avais eu égard à l'action de la Terre qu'à partir du passage au périhélie de 1759, époque à laguelle la comète s'est en effet besucoup approchée de la Terre. M. Damoiseau a fait de même après moi; mais il fallait vérifier si avant le passage au périhélie la comète n'était pas déjà assez voisine de la Terre pour en eprouver des perturbations sensibles. Pai reconnu que le mioyen mouvement diurne pourrait, en effet, en être altéré, queique d'une. manière heaucoup moins considérable qu'il ne l'est par l'action de la Terre aux la comète après le pessage au péchélie. Mais comme tout ce qui touche au moyen mouvement a anr la durée de la période une influence très sensible, il était nécessaire de tenir compte de cette allération. Voici donc, d'après ces corrections, les valeurs des quantités qui déterminent l'époque du passage au périhélie :

Altérations de l'anomalie Mérations du moyen mouvement diurne.

272.

273. + 17010*,48 - + 0",536854

5 - + 393",76 - + 0",028336

28. + 339",20 - + 0",013963

5 - 0",006502

+ 17743",44 + 0",372651.

Le moyen mouvement diurne au périhélie de 1682 est exprimé par  $\frac{360^{\circ} - \Sigma N}{279^{37}}$ . En le nommant donc n, on aura  $n = 45^{\circ},75496$ ; et en nommant  $n' = n + \Sigma N$  le moyen mouvement diurne au périhélie de 1,759, on aura  $n' = 46^{\circ},12761$ .

priphin retenu m'a donné ensuite:

D'après cet éphéméridé, la comète sera probablement visible vers la sin du mois d'août, quoique ées distances à la Terre et su Saleil, soient considérables. A partir de cette époque, elle s'approchera rapidement de la Terre, et dans les premiers jours d'octobre elle en sera très voisine. Sa déclinaison boréale étant alors très grandes elle restera quelques jours sans se coucher; elle s'éloignera ensuite de la Terre à peu près avec la même vitesse jusqu'à son passage au périhelle, qui a lieu le 12,6 novembre. A la sin de ce même mois, elle se perdra dans les rayons du Soleil; ensin, elle redeviendra encore visible, et l'on pourra peut-être l'observes long-temps que se la les dans les rayons du Soleil.

## Sur la Table des positions géographiques;

PAR M. DAUSSY.

Gette table syant été entièrement rélaite dans la Counaisètece des Teme pour 1836, il s'y était glissé encore quelques erreurs on emissions, que j'ai cherché à corriger cette année; j'ai profité pour sula des observations que plusieurs personnes ont hien voulu me communiques. Je dois surtout à l'obligeance de M. le colquel Corabent, d'avoir par ajouter un grand nombre de points dont les positions out été déterminées par les ingénieurs-géographes en Allemagne, en Suide et en Italie, ainsi que les neuvelles déterminations qui résultent de la trimugulation de la carte de France. Je vais rendre compte ici des changement qui est été faits à chaques des sections.

#### SECTION PREMIÈRE. - France.

Les positions d'Ajaccio, Baslia, Calvi et Corte, qui sont les chefs-lieux, d'arrondissemens de la Corse, ont été sjoutées; elles résultent de la triangulation de M. Tranchot, et se trouvent dans la Connaissance des Tenne pour 1393: nous avons toutefois a ugmenté les longitudes de 29°, d'après 140 correction qui a été adoptée pour Livourne, et dont les raisons sont expay sées dans la Connaissance des Tems pour 1836, page 128.

Les nouveaux travaux de MM. les officiers d'état-major chargés de la triangulation de la carte de France nous ont fourni les positions de Hanc-brouk, Sarreguemines, Mirecourt, Neufchâteau, Pontarlier, Beaune, Châtillon-sur-Seine, Arois-sur-Anbe, Chaupent, Vassy, Lure, Mont-brisson et Roanne. Pour compléter autant que possible la détermination de chaque point, j'ai cru devoir ajouter à chaque position sa hauteur, déterminée trigonométriquement au-dessus du miyeau de la mer. Lorsque cette hauteur se rapporte au soumet de l'édifice, elle a été renfermée entre parenthèses, et quand elle se rapporte au sol, elle a été simplement miss à la suite du nom.

Les travaux des ingénieurs-hydrographes sur les côtes de France, en 1834, nous ont donné les moyens de corriger les positions du Havre, de Honfleur, de Fesamp, de Dieppe et de Oystreham, et d'ajouter calles des phages du Hoc et de Quillebrauf.

#### SECTION II. — Iles Britanniques.

Pavais pris les positions de plusieurs phares sur la carte du canal de Saint-George, publiée par Blachfordt en 1826 : réduit à employer une détermination graphique qui présente toujours de l'incertitude, j'ai cherché du moins à m'appuyer sur une carte plus récente et qui portât un caractère d'authenticité. La carte intitulée Vidal bank, off the N. W. vous of Ireland, publics on 1831 par l'hydrographical offlor de Lendres, d'après les travaux du capitaine Vidal, m'a part devois inériter de bespoody la préférence sur celle de Blachfordt : les comparaisons que j'ai fiites des positions qu'elle donne pour Calf-of-Man, Migli-of-Galloway, port Patrick of plasiours autres points, avec les cartes à-grand point des côtes d'irlande du capitaine Mudge, qui sont appuyées sur bais trialegratures, me tent probate qu'on pouvait compter, à moins d'une demissionute près ; sur les positions prises sur la nouvelle carte. J'aî donc ctwolerois y prendre les positions de Corsewal; Pladda; Rhinns of Islay, Killibeg et Tory Island, qui étaient déjà dennées dans la fable, et celles de Barrahead, Fannet et Errishead ou Eagle island, que j'ai ajoutées.

J'ai corrigé aussi les positions des phères de Pile Clare et de South-Arran, d'après une autre carte du capitaine Vidal, intitulée the banks of soundings to the Westward of the British island. Cette dernière carte est, à la vérifé, sur une échelle très petite, et présente par conséquent moins d'exactitude; mais comme la différence en longitude était de 6 à 7 minutes, j'ai pensé que cette quantité ne pouvait être attribuée à l'incertitude du pointé.

Les longitudes de Sandown, Sandwich, South-Foreland et Pershore ont été corrigées des erreurs qui avaient été faites en les réduisant au méridien de Paris.

#### SECTION III. - Hollande et Belgique.

Presque toutes les positions de cette section ont été tirées de la triangulation de la Hollande par Krayenhoff. J'avais pris ces positions dans la table que M. de Zach a donnée dans sa Correspondance astronomique allemande, vol. VIII et IX; mais m'étant procuré depuis l'ouvrage où Krayenhoff a consigné lui-même les résultats de sa triangulation; et qui est intilulé Recueil des Observations hydrographiques et topographiques faites en Hollande par C. R. T. Krayenhoff (Austerdam, 1813); je me suis arrêté définitivement aux positions données dans cet ouvrage, qui ne différent au reste que d'un petit

nombre de secondes de celles qui sont rapportées dans la Correspondance astronomique, quantité dont ou peut d'autant moins répondre que les calculs ont été faits, en partant de Dunkerque, dans l'hypothèse d'un aplatissement apper ce qui exigerant, par conséquent, de nouvelles corrections si l'on voulait revenir à l'aplatissement solve aujourd'hui.

Les travaux géodésiques exécutes par M. Pranchist dans les Payels Bas, pour rattacher la triangulation dont il était chargé dans les départes temens au-delà du Rhin qui faissient alors partie de la France, avec la chaîne de la méridienne, m'ayant été communiqués au dépôt de la guerre, j'ai corrigé de quelques secondes les positions de Malines, Montaigu. Buyemonde. Tongres et Vanlog qui avaient été prises dans la Correspondence astronomique a tome. VI satisfactor have been due zon all'ai arucdoreinie uni mientani des preitique da Acaderades Sykdnine. Vieland . SECTION IV. Danemark) Subde et Norvège.

La position de Reikianess a été corrigée d'après les derniers calcale des ingénieurs danois qui ont levé la carte d'Islande. Ce point se trouve indiqué dans le 4° cahier de la Descripçon des obtes d'Islande, par M. de Lowenorn, par 63° 48′ 15′ N. et 25° 2′ 40° O. de Paris; mans comme la longitude de Copenhague, qui sert de départ, était supposés de 10° 14′ 45″ B., au lieu de 10° 14′ 20″ que nous avons adopté, nous aurans pour la longitude de Reikianess 25° 3′ 5″. La longitude de l'Île Sandard, en Sandae, était donnée de 14° 37′, d'après Holm, depuis 1789; cappendant une carte de Norvège de Poutoppidan, publiée en 1795, donné pour ce point 3° 55′ E. de Copenhague, aussi d'après Holm; ce qui ferait 14° 9′ 20° E. de Paris. De plus, suivant l'hydrographe auglais Purdy, les ingénieurs dánois auraient trouvé pour ce point 14° 20° L'inque certitude qu'il y a sur cette position m'a porté à la supprimer.

J'ai substitué à la position d'Umhea donnée d'après Prosperin, et qui est évidenment fautive, celle donnée par Ricander; enfin, j'ai corrigé une erreur d'un degré sur la latitude de Kiel.

-cu de la latitude de Riel.

SECTION N. -- Russie.

La position de Dagerort a été changée. Le point doumé par Fleurien, était le hourg 1 3 immersions du 1^{er} satellite lui avaient donné gour ce point :

point to a real square says at 19 29,1 so and a series of the says are says at 19 29,1 so and a series of the says are says at 18.56,1 so and a series of the says are says at 18.56,1 so and a series of the says are says at 19.718; and a series of the says are says at 19.718; and a series of the says are says at 19.718; and a series of the says are says are says at 19.718; and a says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are says are

La dernière observation sculmant avait en 6 currespondantis; pour les deux autres, il avait été obligé de corriger les tables par les observations volvines, et même il avait rejeté la secondo comme douteure. Je crois que, ve l'incertatule des observations; on ne deit prendre que la deir nière la longitude dir bourg sera deno de l'appendre que la delle de plante; qui est plus la l'est, sera de rej 55 de l'appendre de ce point sera avait, d'après celle des bourgs de 56 65 que la latitude de ce point le même point, d'après celle des bourgs de 56 65 que la latitude d'appendre pour l'abique d'allère de 5 agré mais comme la longitude de plus pour la longitude diffère de 5 agré mais comme la longitude que l'al adoptés pour l'avait de de himates, il est probable que la laurait, est plus lord de celle de Elist de d'ainates, il est probable que la laurait, est qui la rapprocherait beaucoup de telleu peup a été aussi rectifiée.

SECTION VI. - Allemagne, ou Confédération germanique.

En outre des rectifications qu'un nouvel examen m'a fait apporter à plusieurs points, et qui portsieut principalement sur des fautes d'impression, les communications que sai obtenues au dépôt de la guerre, des résultats des travaux des ingémeurs géographes dans les divers pays que nous avons occupés, tels que ceux de M. Tranchot, en Belgique; de M. Epailly, dans le Hanovre, etc., m'ont mis en état de corriger d'anciennes déterminations, et d'en ajouter de nouvelles de plusieurs villes importantes.

Les positions corrigées sont celles de Augsbourg, Brocken, Brunswick, Cassel, Capo d'Istria, Clèves, Cologne, Parmstadt, Duisburg, Dusseldorf, Emmerich, Hanovre, Neuwerk, Oldemburg, Fola; Tecklemburg, Trèves, Verden, Worms et Kanten.

Les positions nouvelles sont celles de Aix-la-Chapelle, Bonn, Cobinted Creveld, Deux-Ponts, Juliers, Kaiser Lautern, Monte Maggione, Paranage Pirano, Novi, Osera, Promontore, Rastadt, Royignoy et Wesel.

Les positions de Aurich, Emden, Gueldre, Jever et Lier ont été serrigées d'après l'ouvrage de Krayenhoff dont il a été parlé dans la troising section.

J'ai ajouté, d'après les différent auteurs cités dans la tablé, les positions de Elberfeld, Gumbinen, Helmstedt, Marburg, Nauembirg, Nordansen et Postdam: j'ai cru devoir aussi pour ne pas trop augmenter aute table, supprimer les positions de quelques lieux peu importans, tels que Ebersdorf, Elbingerode, Hasenberg, Inselsberg, Jahde, Kaisershen, Kronenburg, Lichtenau, Riesenkupp, Schlukesau, Selmisthen, Schittsingen, Stickhausen, Tepl et Warmensdorf.

La latitude de Leipzig a été augmentée de 6°, d'après les rathuthu de M. Mobius, professeur d'astronomie à l'Université de cette ville.

La position de Lubeck a éprouvé aussi quelques changemens dont je vais donner l'explication.

M. Wurm avait trouvé, par plusieurs occultations, les résultats sivans:

Comme l'observation du 5 avril 1825 est plus complète que les autres; il obtient ainsi pour l'observatoire de M. Sahn, 33 22,08 : comme le glocher de Marlentherm se trouve 4,03 plus d'Hest, de manie par les point 33 26,11.

On tenuve encore dans le n° sun des Mitsonemisthe d'active des seurs voyages faits de 1824 à 1828, a obtenu, au moyen de phisique chronomètres, la différence de longitude entre Altona et Hambourg, d'uni part, et l'observatoire de M. Sahn, il a en singi.

Entre l'observatoire de Hambourg et celui de Lubeck. 2 54',04 Entre l'observatoire d'Altona et celui de Lubeck. 3. 1,45

ce qui donne pour Lubeck 88" 16464 et 38" 20',65, et pour le clother d Marienthurm 33" 30',67 : present le milieu entre ces deux détermination, opsanthe pour la longitude de Labeck ; 33 n 26', 39 em 6º 22'6'' : c'ést' à quairis me anis arrêté.

Quedlinburg. La longitude de ce point présente un peu d'incertitude; les trois discristions dont j'ai pris la moyenne différant entre elles de plusieurs infinutels de degré : les voici d'après les calculs de M. Wurm.

Ranage de Mareure uflon. . . 35"25',7 (Monati. ourr sept. 1806)

JEdi. de Saleila . . . . . 1803. . . 35',46,5 ( iden. ) oct. 1805)

Movenne. . . 35.28,8 = 8° 52′ 12″.

Schweithille-La-longitude de ce point a été un peu changée; voici les observations sur lesquelles elle est fondée; elles ont toutes été calculées par Mi-Wurin.

Hilly March & British a face

10 oct. 1802 & Poissons... 56.24,4

-1c - 1c - 1, 2 avril 1803 ; Lion ... . . . . 56,38,7

16 juin 1806 écl. de O. . . . 56.45,6

Moyenne. . . . . 66.32,4 == 14.86.

Travemunde (le phare). D'après les travaux exécutés en 1811 par M. Beautemps-Beaupré, pour lever le plan de la baie de Lubeck, le phare de Travemunde se trouve 12^m 6' à l'est et 5'32" au nord de la grande église de Lubeck, dont nous avons déterminé ci-dessus la position.

# SECTION VII. - Hongrie, Dalmatie, Grèce, etc.

o. Laposition de Castel Tornèse a été corrigée d'après la détermination de M. Peytier; celles de l'île Sainte-Catherine et de Ténédos ont été supprimées comme appartenant à l'Asio; muis j'ai cru devoir sjouter, d'apuis M. Peytier, les pasitions d'Égine, Saint-George d'Arbora, Hydra, Lépanté, Modon, Nauplie, Navarin, Patras, Sparte, Strophade (ile) et Trapolites.

#### SECTION VIII. - Italie et Suisse.

Cette section, qui contient les positions de l'Italie et de la Suisse, est celle qui a reçu le plus d'augmentations. J'ai rectifié un grand nombre de positions, et ajouté 62 nouvelles déterminations, d'après les résultats des opérations géodésiques assessées en Suisse et dans

l'Italia: mocrioure per les ingénieure géographes; il det virepent à désirer que que importane travaux, qui cont d'un grand lathit neur la sécrephia coient publiés dans tons leurs détails les diterminations que i'en ai tirées étant le misultat des calenis faite à une apoune où l'on suppossit l'aplatissement de la Taune de ont été obtenues dans cette hypotèse. Toutes celles de l'Italie mpt rieure ont en pour point de départ le dûme de Milan, dant la poltion géographique était supposée lat. 45°27 347,0, long. Grés 41,6. Les observations de signaux de feu, faites our le parallèle intent avant donné pour la longitude de ce dôme 6º51'5', j'ai cru deter retrancher 11",6 de toutes les longitudes dennées par les feminieus néographes. Il ne faut pas croire, au reste, que les autualists afedisignes, suoiqu'elles donnent apèc une grande préciales les parities relatives des points voisins, puissent donner à la seconde les pudibits géographiques absolues, surtout lereque le electe triguementrique et un peu étendu. Les irrégularités du globe terrestre desposent à u qu'on puisso déduire d'une sèrie de triangles les attenes résultats qu'on obtiendrait d'observations astronomiques directes. C'est aurient des l'Italia que se sout manifestées la plus fortement un differente ai tre les messures trigosponattriques et autronomiques , diffirement quibien qu'aujourd'hui elles présentent quelque chees d'insertais ets géographes, serviront sans doute dans la suite à faire: canna constitution intime du globe.

#### SECTIONS IX, X at XL

Ces parties n'ont éprouvé d'autres changemens que quelques évirections de fautes qui étaient échappées à la première révision.

#### SECTION XII. - Hes du grand Océan.

Les positions des iles Saint-Augustin, Aurupig et Bunkey ent in prises sur la carte des lies Carolines de M. Duperrey, corrigée en 1836

#### SECTION XIII. - Afrèque.

Les travaux de M. Bérard, qui vient de terminer la recommissante des côtes de la régence d'Alger, m'ent servi, à sjouter à cette section quelques positions hien déterminées: ce sont celles de Arson, House, Bougie, la Calle, Cercel, Gello, Celombi (Ne), Cep de Fer, la Galite, Jigeli, Mostagonem, Riegeum (Ne), Taharque et Zafaripae (Nes). J'ai sussi

icotrigit, d'apuis les dergisse dals, des positions qu'il avris biténués pudat de many de Bonne-Espérance et celle de The Mainte-Piglem de Bonne-Espérance et celle de The Mainte-Piglem sinvisté d'objet de més rechardres appointes ; les efficierés fournife aque établis dans des deux points devant mainte ces deux points au manière certaine ces deux points dens de publique est tous importants pour les manighteurs.

Japaner 1886, la longitude de la ville du Caprenaité de dottée dans la Commission des Tems de 16° 2' 45°. Cette détermination, nimis qu'en peut le noirellain le volume de 1785, était le moyenne des négations par La Caille, qui avait déterminé la longitude de sap abservations de 1° 4° 1° ½ = 18° 4' 3°, et par Short qui, par des abservations de dégens et Dinen, avait trésivé 1° 4° 18° maji6° 3' 15° dissabage déciment le défende de 18° 8' 6° par este moyenne entre les abservations de plusieure messaonnes Le capitaine Open denuie pour le Château abruiné Estim, M. D'Urrille, par le trènsport du temp, depuis le port Louis de l'Ilo-de-France, trouve 16° 7' 11".

Comme une grande partie des positions déterminées par Owen, sur les character subis, sinsi qu'il le dit lui-même, la correction qu'e sersit mispine pour se point; on ne saurait chercher à déterminer cette formitale auss trop de présision.

L'établissement d'un observatoire au Cap nous donne les moyens d'arriver à ce but; déjà, dans le 6^{me} volume des Mémoires de la Societé astronomique de Londres, en trouve le résultat de calculs faite par M. Henderson d'un grand nombre de passages de la Lune comparée à des étoiles voisines. Ces observations avaient été faites en 1829 et 1830 par M. Fallows, et l'on avait en des observations correspondantes à Gréenwich, Cambridge, Abo et Edimburg, j'ai cru devoir, pour assurer encore plus cette détermination, calculer tous les passages aemblables qui out, été observés en 1832 et 1833 par M. Hendesson, et qui out, été observés en 1832 et 1833 par M. Hendesson, et qui out, été observés en 1832 et 1833 par M. Hendesson, et qui out, été observés en 1832 et 1833 par M. Hendesson, et qui out, été observés en 1832 et 1833 par M. Hendesson, et qui out, été observés en 1832 et 1833 par M. Hendesson, et qui out, été observés en 1832 et 1833 par

Je vais rapporter ici les résultats des céleuits de M. Henderson; on en trouvera les détails dans les Mémoires de la Société astronomique, temé Viscours rassessants en les les la société astronomique,

ı* avril	37,30				
3	35,36				
Moyenne des 17 1h	4m33',89				

Pour parvenir au résultat final, nous remarquerons que dans toutes ces comparaisons le nombre des observations du second bord est toujours heaucoup moindre que celui des observations du premier. Si nous réunissons toutes les longitudes obtenues par chaque bord, en combinant les calculs de M. Henderson avec les nôtres, nous aurions

Par 97 observations du 1er bord, longitude moyenne.. 1h4m36,02 1.4.30,81. Par 24 observations du 2° bord,

Si donc on croyait devoir prendre la moyenne entre les résultats des observations de chaque bord, on aurait pour résultat final

mais si l'on joignait toutes les observations ensemble, sans distinction de bord, on aurait

$$1^{\lambda} \dot{4}^{m} \dot{3}4',99 = 16^{\circ} 8' 45''.$$

La différence entre ces deux résultats est assez petite pour qu'on puisse prendre l'un ou l'autre; nous adopterons cependant le premier; qui nous

Digitized by Google

paraît offrir plus de probabilité, parce que le nombre des observations du second bord est déjà assez grand pour qu'on puisse espérer que les erreurs accidentelles se sont compensées, et que la différence qui reste peut être attribuée à une cause constante qui tiendrait au genre d'observations.

La longitude que nous venons de déterminer est celle de l'Observatoire, mais comme ce point se trouve à quelque distance de la ville, ¿zi cru nécessaire, dans l'intérêt des marins qui ont souvent occasion de régler leurs chronomètres au Cap, de donner aussi la longitude d'un des points de la ville. Or, les travaux du capitaine Owen nous donnent pour la différence entre l'Observatoire et le mât de pavillon du château 2'48". Ces deux points étant d'ailleurs sur le même parallèle, on aura donc pour la position du château,

Latitude, 33° 56′ 3″ S.; longitude, 16° 5′ 33″ E.

M. Henderson a déterminé aussi, que la pointe du Cap se trouvait sous le même méridien que l'Observatoire; j'ai cru devoir ajonter ce point, en prenant la latitude donnée par Owen.

La position de la ville du Cap ayant; ainsi que nous l'avons dit plus haut, servi de départ au travail du capitaine Owen sur cette côte, et la longitude que nous adoptons étant plus forte de 5'9" que celle qu'il avait prise, nous avons appliqué la même correction de 5'9" aux longitudes d'Algoa, Angra-Pequena, Benguela, Corientes (cap), Delagoa (baie), Falsebay, Lagulas (cap) et Saint-Paul de Loanda.

Sainte-Hélène. Les observations des passages de la Lune faites à l'observatoire établi récemment à Sainte-Hélène, et qui sont rapportées dans les Mémoires de la Société astronomique, nous donnent aussi les moyens de déterminer directement la longitude de ce point important. Je vais rapporter ici les résultats des calculs que j'ai faits pour obtenir cette longitude, en employant pour comparaison les observations de Greenwich et de Cambridge, que j'ai prises dans les recueils d'observations de chacun de ces Observatoires, celles de Makerstoun et d'Edimburgh, que l'on trouve dans les Mémoires de la Société astronomique, enfin, celles de Bogenhausen, Cracovie, Abo et Prague, qui sont rapportées dans différens numéros des Astronomische Nachrichten. Les longitudes de ces observatoires étant

Bogenhausen. . . 37^m 5' 2 Craeovie. . . . . . 70,28,0 Abo.. . . . . . . . 79.47,0 · Comme ici nous n'avons eu que 3 observations du second bord, j'ai cra devoir les réauir avec celles du premier bord, en les indiquant seulement. Longitude de l'Observatoire de Sainte-Hélène par les passages de la Lune et des étoiles voisines: 1830. 5 janvier.... Edimburgh.... 32m o',53 6..... 	us lui donnerent, entre le fort Amster-

la différence de longitude entre le Cap et Seinte-Hélène, dans une tradversée de 14 jours. Ses observations lui donnérent, entre le fort Amsterdam au Cap et James-Town, 14 36/38', o. Le point d'observation à Sainte-Hélène se trouvait 3' de tenis à l'est de l'observatoire, et le fort Amsterdam, d'après le capitaine Owen, est 12', 66 à l'onest de l'observatoire du Cap. Les chronomètres du capitaine Roster donneraient donne entre ces deux points rh 36' 46', 66. Les longitudes que nous venums de déterminer donneraient pour la même différence 14 86' 46', 26', 66 se

qui offre une confirmation des résultats auxquels nous sommes par-

Madère. Nous avions déjà adopté pour la longitude de Funchal, à Madère, la position qui avait été déterminée en 1822 par M. Tiarks, au moyen de 17 chronomètres; elle était de 1^h 17^m o',7. Cette longitude a encore été confirmée par les observations du capitaine Foster en 1828, qui, au moyen de 11 chronomètres, a trouvé pour cette même longitude 1^h 17^m o',6. Les observations de distances de la Lune au Soleil, faites en très grand nombre par le capitaine Sabine, lui avaient donné 1^h 17^m 1,6; une occultation observée par M. Rumker et calculée par Wurm donne 1^h 17^m 2',6; enfin, M. Rumker trouvait par ses chronomètres 1^h 17^m o',2. On peut donc regarder la longitude de ce point comme très exactement déterminée = 1^h 17^m o',2 ou 19° 30' 10".

Sainte-Croix de Ténérisse. Par une traversée de 4 jours, le capitaine Foster alla de Funchal à Sainte-Croix de Ténérisse: 13 chronomètres lui donnèrent pour la disséreace de ces deux points 2^m 40',15. Les dissérences extrêmes n'étant que de 2^m 37'05 à 2^m 42',54, on peut donc regarder aussi cette détermination comme très exacte, et prendre pour la maison du consul anglais à Saint-Croix, lat. 28° 28' 1", et long. 1^h 14^m 20',3 == 18° 35' 15"; ce qui, rapporté à l'extrémité du môle, donne pour ce point, lat. 28° 27' 49", et 18° 35' 8". Dans l'expédition de M. Roussin sur les côtes d'Afrique, M. Givry avait trouvé pour cette position 28° 27' 59", et 18° 33' 30"; je pense que la longitude déterminée par le capitaine Foster, étant fondée sur un plus grand nombre de chronomètres et dans une traversée très courte, présente plus de certitude.

Bermudes. Comme les observations faites dans le voyage du capitains Fostex sont nombreuses, et que sur la pointe E. de Cuba elles sont d'accord avec celles de l'errer, j'ai adopté sa position des Bermudes, ainsi que celle de la ville Delgada à Saint-Michel des Açores.

Fernando de Noronha. La position de cette île présentait quelque incertitude. M. Lartigue, en 1825, s'appuyant sur les positions de la côte du Brésil, avait déterminé le pie par, lati 3° 50'34"S., et long. 34° 46'58"; Le capitaine Beechey avait trouvé pour l'église 3°52'55"S., et 34° 36'54, mais l'un et l'autre avaient observé en mer.

Le capitaine Foster a fait deux séjours dans cette île, et il en à déterminé la position par rapport à Funchal et à l'île de l'Ascension, au moyen de ses chronomètres qui, à cause de leur nombre et de leur accord, présentent une grande probabilité d'exactitude. Il a trouvé ainsi entre Funchal et Fernando de Neconha (maison du gouverneur) 1^h 1^m 44',12, ce qui donne pour ce point 2^h 18^m 44',1 = 34° 41' 10". Dans une antre

Digitized by Google

M. Tiarks, qui a discuté les observations du aspitaire. Faster, adopte définitivement pour la longitude de ce point at 9",34',38 de Greunvich, ou 2" 18" 54',0; mais il n'a employé que la lisison de ce point avec Saintes. Hélène par l'intermédiaine de l'Accension, et il a supposé que l'entent devait se trouver tout entière dans la traversée de Funchel à l'enumée de Roronha.

La latitude de la maison du gouverneure eté obtanue par planieurs chi servations du soleit et d'étoites de 8º 40'50",5 35. Le pio ou la Byrannide étant 10". Section of the Companies of the Companies and the state of the state of the second contract of the

SECTION XIV. Amérique septentrionale.

J'ai ajouté à cette section la position du Cap Farewell, d'après le capitaine Graah; elle se trouve rapportée dans le Nautical Magazine, cahier de lévrier 1833. on the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of th

La position de Sainte-Croix a été corrigée : j'ai adopté le dernier résultat auquel est parasses M. Winne en calculant diverses occultations observées par M. Lang, et qui sont rapportées dans les Astronomiche nachrichien, n° 200, p. 136.

M. Zahrtmann ayant déterminé avec beaucoup de précision la différence entre son observatoire à Saint-Thomas et celui de M. Lang à Sainte-Croix, de 54',91, il a été facile de conclure du premier la position du second.

Les observations faites dans le voyage du Chanticleer, capitaine Foster, qui ont été discutées avec beaucoup de soin par M. Tiarks, m'ont donné les positions, de la pointe Morant (Jamaique), qui s'accorde très bien avec celle de Port-Royal de la même île déterminée par le capitaine Sabine, de l'une des îles Crooked, de Barracoa et du Cap Maizi sur l'île de Caba; cependant, je n'ai pas adopté pour ce dernier point la latitude qui ce trouve rapportée (20° 4′28″). Ferrer et les Espagnols qui out levé la carte de Guba, s'accordent à placer ce point par 20° 16′30″, ou 20° 16′40″; la latitude de Barracoa, observée dans le même voyage, s'accorde avec les cartes; il n'est pas probable que sur une aussi petite distance que celle qui sépare ces deux points, on ait pu faire une erreur, en levant la carte, de 12 minutes; j'ai donc supposé que la latitude du Cap Maixi, donnée dans le voyage de Foster, était erronée, et j'ai conservé 20° 16′30″.

Dans l'embarras de choisir entre ces 5 déterminations, qui toutes présentent une certaine exactitude, j'ai pris le parti d'adopter la moyenne 63° 53′ 15, en attendant que de nouvelles observations viennent lever toute incertitude.

#### SECTION XVI. - Amérique méridionale.

Nous avons ajouté à cette section les positions des principales villes du Pérou et de la Bolivia, qui ont été déterminées par M. Pentland, et dont on trouve les détails à la page 36 de ce volume. Ces positions sont celles de Arequipa, Chucnito; Chuquisaca ou la Plata, Cochabamba, Copacabanha, Misque, Moquegua, Oruro, la Paz, Potosi, Puno, Sicasica et Taona.

Les observations du capitaine Foster auraient pu nous fournir de nouvelles déterminations pour plusieurs points de cette côte; mais la liaison qui existe entre toutes les positions du Brésil ne permet pas de toucher aux unes sans changer également toutes les autres. D'un autre côté, toutes les déterminations du capitaine Foster étant le résultat d'observations chronométriques nombreuses et qui paraissent très exactes, il était difficile d'en adopter quelques-unes seulement; j'ai donc préféré laisser subsister cette section comme elle était, mais je pense qu'il sera utile de donner ici le tableau des résultats obtenus par M. Tiarks d'après les observations du capitaine Foster, et dont nous avons déjà fait usage dans les sections précédentes.

EXTRAIT DU RAPPORT DU D' TIARES, SUR LES OBSERVATIONS. CHRONOMÉTRIQUES DU CAPITAINE FOSTER, EN 1828, 29 27 30.

Désignation des points de station,

Falmouth. Le mat de pavillon du château Pendennis.

Madère. Le jardin du consul anglais, à Funchal. Longitude, 47-28,09 à l'O. de Falmouth.

Ténérisse, à Sainte-Croix. Maison du cousul angleis, 240 pieds anglais au N. 20° O. du fort San Pedro (*). La latitude de ce point a été trouvée par des observations de la Polaire et d'Antarès, faites avec un cerule répétiteur de 28° 28′ 0°,85 N. Différence de longit, avec Funchal, 22 40°,58 E.

Saint-Antoine (ile). La station a été faite sur le rivage près de la pointe ouest de l'île, et au pied de la montagne la plus élevée. Latitude par des hauteurs circumméridiennes du soleil prises avec un sextant, 17°1'4",4.

^(*) Tous les relèvemens ont été cotrigés de la déclinaison de l'aiguille, et se rapportent au Nord du Monde.

La pointe sud de l'île restait au 6. 9°4° E; le sommet de la plus haute montagne au N. 77° E., distance environ deux milles et demi, déterminée par un angle d'élévation de 26°. La hauteur de la montagne étant supposée, d'après Horsburgh, de 7400 pieds anglais au-dessus du niveau de la mer, le sommet de cette montagne se trouve par conséquent 3°,37 au nord et 10',18 (de tems) à l'est de la station. Différence de longitude avec Funchal, 33° 42,34.

Rocher Saint-Paul, ou Penedo de San Pedro. Ce rocher a été relevé: au N. 80° E. du Chanticleer, distance estimée environ 12 milles. La latitude déduite de l'observation de midi, était o° 56′ o″ N. Le rocher était, 2′ ¼″ au nord, et 47′,28 à l'est du point où les chervations ont été faites; ce qui le place par o° 58′ 4″ N., et 49^m 28′,89 à l'ouest de Funchal. Fernando de Noronha. La maisen du gouverneur. La latitude a été trouvée, par plusieurs abservations du Soleil et d'étoiles, de 3° 49′59°,47 S. Le pic ou pyramide restait au S. 71° 50′ O. à la distance de 3540 pieds, et par conséquent 10″,93 au sud et 2′,22 (de tems) à l'ouest du point d'observation dout les chronomètres ont donné la différence avec Funchal, de 1^h 1^m 44′,12.

Cap Frio, Latitude du point d'observation, 22° 58' 39',63 S. par des hauteurs circumméridiennes du Soleil prises avec un sextant. Le cap Frio restait au sud 25° 46' est du point d'observation à la distance d'environ \(\frac{1}{4}\) de mille, par conséquent \(\frac{40}{5}\),52 au S. et 1',42 à l'est. Le point de station a été trouvé par les chronomètres 38" 18',17 à l'O. de Fernando de Noronha La variation du compas observé à terre était de 1°7' E.

Rio Janeire. Station sur l'île Villegagnon, près du puits au milieu de l'île, le Pain de Sucre restant au S. 2°50' E. Des hauteurs du Soleil, prises avec un sextant, ont donné pour la latitude de ce point 22°54'31",07; sa différence de longitude avec Fernando de Rorenha a été trouvée de 42°591,70.

Ile Sainte-Catherine. Fort Santa-Cruz d'Anhatomirim, près du mêt de pavillon. Latitude, 27° 25′ 29′ 18′ 8., moyenne de 11 observations faites par les capitaines Foster, Roussin et Stokes. Longitude, 21° 39′,77 O. de Rio Janeiro.

Montevideo. Station sur l'île Ratos, près de l'angle S.-E. du fort. La latitude à été trouvée de 34°54′25″,7 par 32 observations de hauteurs du Soleil et d'étoiles, prises avec un cercle répétiteur. Longit. 52″18″,07 à l'ouest de Rio Janeiro.

Iles des États. Au fond du port Cook, où il y a un isthme has par dessus lequel on peut transporter un bateau de l'autre côté de l'île, le point de station était au pied de la terre haute, du côté ouest de l'isthme, quel-

ques pieds seulement au - dessus de la marque de la pleine mes dessus de la marque de la pleine mes dessus de la marque de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la pleine mes de la

Anse Saint-Martin, sur la Terre-de-Eeu, puès du cap Horn. Dur point de station l'extrémité N. de l'île Chanticleur paraissait un peu à l'ouest d'une pointe qui s'avance dans l'intérieur de l'anse, près du capt sud; et la partie sud de l'île Jerdan un peu ouverte du cap mord, de point se trouvait à environ trente verges au-dessus de la marque de la ploint mer, sa latitude a été trouvée, par plusieurs hauteurs circumméridizance du Soleil prises que un sextant, de 55° 51'19",83. Longit:, n 4° 51.95 à l'année du port Cook (île des États).

Ile Deception (South Shetland). Anse du gendule, côté est de l'Ileij à environ 4000 pieds du sommet du mont Pond's qui restdit au Nace E, Le latitude a été obtenue par plusieurs observations de lauteurs du Spleil. prises avec un sextant et un cercle à réflexion, elle à été trouvée de 62°56′ 11″, 4 S. Longitude, 13°50°;09 à l'est du part Cook (de den Étate )

Anse Saint-Martin. Terre de Feu. La seconde atation a seté, fine à 580 pieds au S. 84° E. de la première La différence de longitudes entre les deux stations ne serait donc que o',oı. Les chronoineres ont donné pour différence de longitude entre ca point et l'ille Decèption, 27° 54',91.

Mossel (baie). L'île Seal restait au N. 22°31'O. à la distance de Segu pieffe du point de station. La latitude a été trouvée par des hauteurs du Soleife observées avec un sextant, de 34° 10′ 17″; la longitude, de 5º 587.587,861 à l'est de l'anse Saint-Martin. La déclinaison de l'aiguille a été observée. de 35° 16′ N.-O.

Baie de la Table. Bastion S.-E. de la batterie d'Amsterdam. Le pie du Diable restant au S. 20° 31' E. à 16,600 pieds de distance; da latitude de la station déterminée avec un sextant a été trouvée de 33° 54' 36',6, ce qui donne pour la latitude du pic 33° 57' 10",2. Longitude, 14" 45' 39' à l'encell de Mossel (Bay).

Sainte-Hélène. Une première station a été faite à Jamestown dans le maison du gouverneur; M. Henderson pense que cette station doit être 3' de tems à l'est de l'observatoire. Une seconde station a été faite à l'extrémité ouest du fort, dans Lemonvalley. La latitude de ce point a été observée de 15° 56′ 7″, 15. La différence de longitude avec la première station était de 6″,92, dont il était plus à l'ouest. La première station avait été trouvée de 1° 36° 33',00 à l'ouest de la batterie d'Amsterdam. Déclinaison de l'aiguille, 24°37'. O.

Ile de l'Ascension, Barrack-Square. La latitude a été obtenue par 40 abservations de hauteurs circumméridiennes du Soleil; elle est de 1°55'28',4-S.

Longitude, 34" 41',44' à l'ouest de Sainte-Hélène (Lemon Valley). Déclinaison de l'aiguille, 20° 10' O.

Fernando de Noronha. La maison du gouverneur, comme précédemment Longitude, 1th 1 1st 57',02 O de l'Ascension.

Maranham, pointe San-Francisco. Le point destation était au S. 15°30' E. de la maison du consul, à 425 pieds de distance, et au S. 24°21' E., à 4928 pleds de la cathédrale. Longitude, 47°33',91 O. de Fernando de Noronha. Déclinaison de l'aiguille, 31' O.; inclinaison, 22°20',9 N.

Para. Station dans le fort San-Pedro de Lasca. Longitude, 16⁴⁵,80 O. de Maranham. Déclinaison de l'aiguille aimantée, 1° 14' E.; inclinaison, 23° 27',4 N.

Ile de la Trinité. Fort Saint-David, ou fort de mer au port d'Espegne. Longitude, 52^m o',80 O. de Para. Inclinaison de l'aignille aimantée, 38° 50′,5 N.

La Guayra. Le fort près de la jetée de bois. Longitude, 21^m 40',27 à l'ouest du port d'Espagne.

Porto-Bello. Fort Jeronymo. Latitude, 9°32′30″ N.; longit, 50"534,17 de la Guayra; inclinaison de l'aiguille, 32°42′,3 N.

Chagre, près de l'angle est du château San-Laurenzo, situé sur le cêté N.-E. de l'embouchure de la rivière de Chagre. L'atitude, par des hauteurs circumméridiennes du Soleil et des étoîles, 9° 18' 38" N.; Iongitude, 17 22',94 O. de Porto Bello; déclinaison de l'aiguille aimantée, 6° 27' 50" E.

La Jamaique. Pointe Morant, à l'extrémité est de l'île. Latitude déterminée par plusieurs hauteurs circumméridiennes du Soleil, 17°55'26". Longitude, 15" 15',20 à l'est de Chagre; déclinaison de l'aiguille, 5' 13' E. "Barracoa, à la partie orientale de l'île de Cuba. Le fort de la pointe du vent du port de Barracoa, près du mât de pavillon. Lat., 20°21'36" N. Longit., 22" 0',43 est de Chagre. Déclinaison de l'aiguille, 3°17' E. Inchiason, 50°6',9.

Bermudes, fort Sainte-Catherine, île Saint-George. Latitude déterminée par des hauteurs circumméridiennes du Soleil et d'étoiles, 32°23'13" N. Longitude, Bgmx8',34 E. de Barracoa; déclinaison de l'aiguille, 6°59' E.; inclinaison, 65° 18' 1" N.

"Cap Mairi. Pointe orientale de Cuba. Latitude, 20°4' 28" (*); longitude, 1727,65 à l'est de Barracoa; déclinaison de l'aiguille, 2°27 est. l'Hes Crooked, fles du passage, extrémité méridionale de Castle La-

⁽a) Forrer et les officiers espagools qui out levé le plan de l'île de Cuba placeot cerre pointe par 20° 16' 30" et 20° 16' 40".

land. Latitude, 22° 7' 26" N.; longitude, o" 40',65 est de Barracoa; déclinaison de l'aiguille, 4° 27' est.

Ile Saint-Michel. Le mât de 'pavillon du château de Saint-Braz à la ville Delgada. Latitude déterminée par des hauteurs circumméridiennes du Soleil, 37° 43′ 58″; longitude, 2h 35^m 58′,01 à l'est des Bermudes; déclinaison de l'aiguille, 24° 31′ ½ 0.; inclinaison, 67° 3½′,1.

Falmouth. Mât de pavillon du château Pendennis. Long. 1^h22^m39',30 à l'est de Saint-Michel; déclinaison de l'aiguille, 25° 25' O.; inclinaison, 68° 5',74.

M. Tiarks, après avoir discuté et comparé ces observations, partant de la position de l'observatoire du cap de Bonne-Espérance, déterminée par M. Henderson, de 1^h 13^m 55',0 E. de Gr., et de celle de l'observatoire de Sainte-Hélène, de 22^m 50' O. de Gr., et répartissant les erreurs trouvées dans les différentes traversées, s'arrête enfin aux longitudes suivantes, que nous avons réduites au méridien de Paris.

NOMS	LATITUDE.	LONGITUDE		
DES LIEUX.		en tems.	en degrés.
